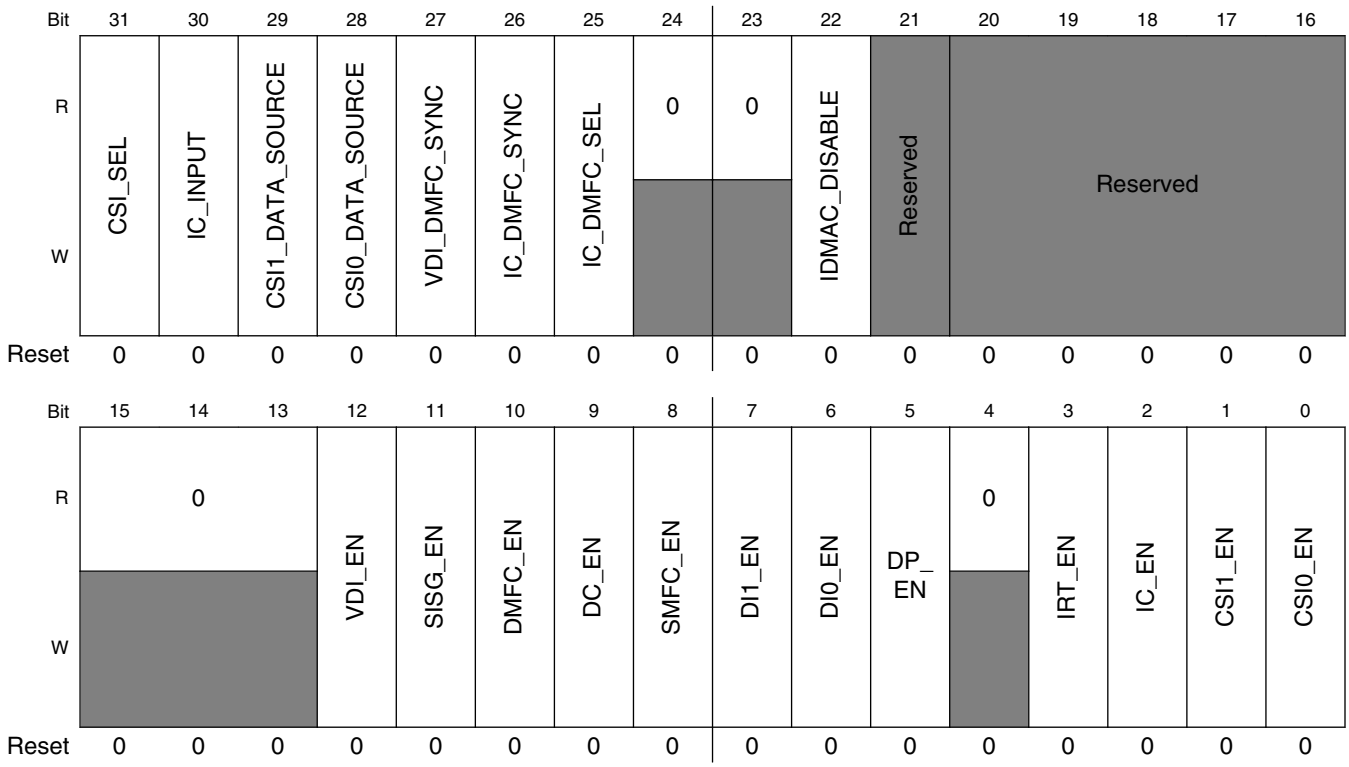
37.5.1 Configuration Register (IPUx_CONF)

Address: Base address + 0h offset



IPUx_CONF field descriptions

Field	Description
31 CSI_SEL	CSI select bit; This bit selects manually between the 2 CSI's. This bit defines which CSI is the input to the IC. This bit is effective only if IC_INPUT is bit cleared 0 CSI0 is selected 1 CSI1 is selected
30 IC_INPUT	IC Input select bit. This bit selects manually between the 2 inputs to the IC 0 CSI0/1 is selected; In order to select between the CSIs use the CSI_SEL bit. 1 VDI
29 CSI1_DATA_SOURCE	CSI1 data Source This bit selects what is the data source for the CSI1. This is a static mux that should not be changed while CSI1 is working. Data is handles differently if the source is MCT (MIPI) or parallel interface. 0 Parallel interface is connected to CSI1 1 MCT (MIPI) is connected to CSI1
28 CSI0_DATA_SOURCE	CSI0 data Source This bit selects what is the data source for the CSI0. This is a static mux that should not be changed while CSI0 is working. Data is handles differently if the source is MCT (MIPI) or parallel interface.

Table continues on the next page...

IPUx_CONF field descriptions (continued)

Field	Description
	0 Parallel interface is connected to CSI0 1 MCT (MIPI) is connected to CSI0
27 VDI_DMFC_SYNC	This bit enables the direct path VDIC -> IC_VF -> DMFC for sync flow. If this bit is set IC_DMFC_SEL must be set. 0 the flow is disabled 1 the flow is enabled
26 IC_DMFC_SYNC	IC to DMFC Sync flow This bit defines if the direct flow between IC to DMFC is synchronous or asynchronous 0 async flow 1 Sync flow
25 IC_DMFC_SEL	IC to DMFC select Selects the DMAIC_1 (channel 21) channel's connectivity between the IC and the DMFC 0 DMAIC_1 (channel 21) is routed to the IDMAC 1 DMAIC_1 (channel 21) is routed to DMFC In case DMFC was selected the IDMAC_CH_EN[21] must be clear.
24 Reserved	This read-only field is reserved and always has the value 0.
23 Reserved	This read-only field is reserved and always has the value 0.
22 IDMAC_DISABLE	Image DMA controller (IDMAC) disable bit. This bit allows the user to turn off the clock of the IDMAC if the use case permits it. By default the IDMAC is enabled. 0 IDMAC is enabled 1 IDMAC is disabled
21 -	This field is reserved. Reserved.
20–16 -	This field is reserved. Reserved
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 VDI_EN	VDI enable bit. This bit must be cleared if the ISP_EN bit is set. 0 VDIC is disabled 1 VDIC is enabled
11 SISG_EN	Still Image Synchronization Generator (SISG) Enable bit 0 SISG is disabled 1 SISG is enabled
10 DMFC_EN	Display's Multi FIFO Controller sub-block (DMFC) Enable bit 0 DMFC is disabled 1 DMFC is enabled
9 DC_EN	Display Controller sub-block (DC) Enable bit

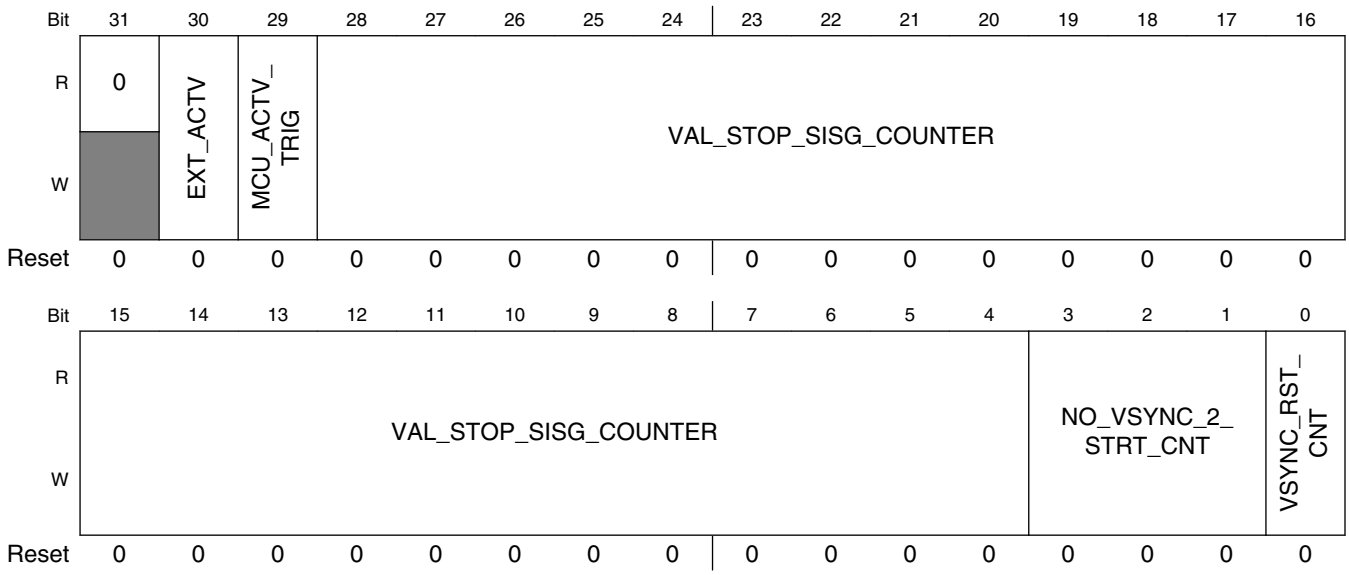
Table continues on the next page...

IPUx_CONF field descriptions (continued)

Field	Description
	0 DC is disabled 1 DC is enabled
8 SMFC_EN	Sensor's Multi FIFO Controller Sub-block (SMFC) Enable bit 0 SMFC is disabled 1 SMFC is enabled
7 DI1_EN	Display Interface Sub-block 1 Enable bit 0 DI1 is disabled 1 DI1 is enabled
6 DI0_EN	Display interface Sub-block 0 Enable bit 0 DI0 is disabled 1 DI0 is enabled
5 DP_EN	Display processor Sub-block Enable bit 0 DP is disabled 1 DP is enabled
4 Reserved	This read-only field is reserved and always has the value 0.
3 IRT_EN	Image Rotation Sub-Block Enable bit 0 IRT is disabled 1 IRT is enabled
2 IC_EN	Image Conversion Sub-Block Enable bit 0 IC is disabled 1 IC is enabled
1 CSI1_EN	Camera Sensor Interface 1 Enable bit 0 CSI1 is disabled 1 CSI1 is enabled
0 CSI0_EN	Camera Sensor Interface 0 Enable bit 0 CSI0 is disabled 1 CSI0 is enabled

37.5.2 SISG Control 0 Register (IPUx_SISG_CTRL0)

Address: Base address + 4h offset



IPUx_SISG_CTRL0 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 EXT_ACTV	External Active Define if an external active trigger will start the counters. The external active trigger is an input signal to the IPU called ext_actv_trig
29 MCU_ACTV_TRIG	Reserved, should be cleared.
28–4 VAL_STOP_SISG_COUNTER	SISG Stop Counters value. This is a predefined value that stops the SISG counters. The user should write to this field the N-1 value of the desired value.
3–1 NO_VSYNC_2_STRT_CNT	VSYCs to Start Counter This bits define how many VSYNCs signals will be counter before activating the SISG counters. If set to 0 starts immediately. If set to N (1..7) starts after N VSYNCs.
0 VSYNC_RST_CNT	VSYNC Resets counters Defines if the counters are stooped following VSYNC or when the counters reach a pre defined value (VAL_STOP_SISG_COUNTER) 1 The counters are stopped at VSYNC 0 The counters are stooped when the counters reach the VAL_STOP_SISG_COUNTER value.

37.5.3 SISG Control 1 Register (IPUx_SISG_CTRL1)

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_SISG_CTRL1 field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13–8 SISG_OUT_POL	SISG_OUT_POL This bits defines the polarity of the SISG output signals 1 active high 0 active low
7–5 Reserved	This read-only field is reserved and always has the value 0.
SISG_STROBE_CNT	SISG Strobe Count The SISG can repeat the sequence for up to 32 cycles; this is used for generating a train of pulses.

37.5.4 SISG Set<i> Register (IPUx_SISG_SET_i)

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_SISG_CLR_i field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
SISG_CLEAR_i	SISG CLR <i> value These bits define the clear value of the SISG counter #<i>

37.5.6 Interrupt Control Register 1 (IPUx_INT_CTRL_1)

This register contains part of IPU interrupts controls. The controls of EOF (end of frame) of DMA Channels interrupts [31:0] can be found in this register.

Address: Base address + 3Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IPUx_INT_CTRL_1 field descriptions

Field	Description
31 IDMAC_EOF_EN_31	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
30 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
29 IDMAC_EOF_EN_29	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
28 IDMAC_EOF_EN_28	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
27 IDMAC_EOF_EN_27	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
26 IDMAC_EOF_EN_26	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IDMAC_EOF_EN_25	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
24 IDMAC_EOF_EN_24	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
23 IDMAC_EOF_EN_23	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
22 IDMAC_EOF_EN_22	Enable End of Frame of Channel interrupt. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number.

Field	Description
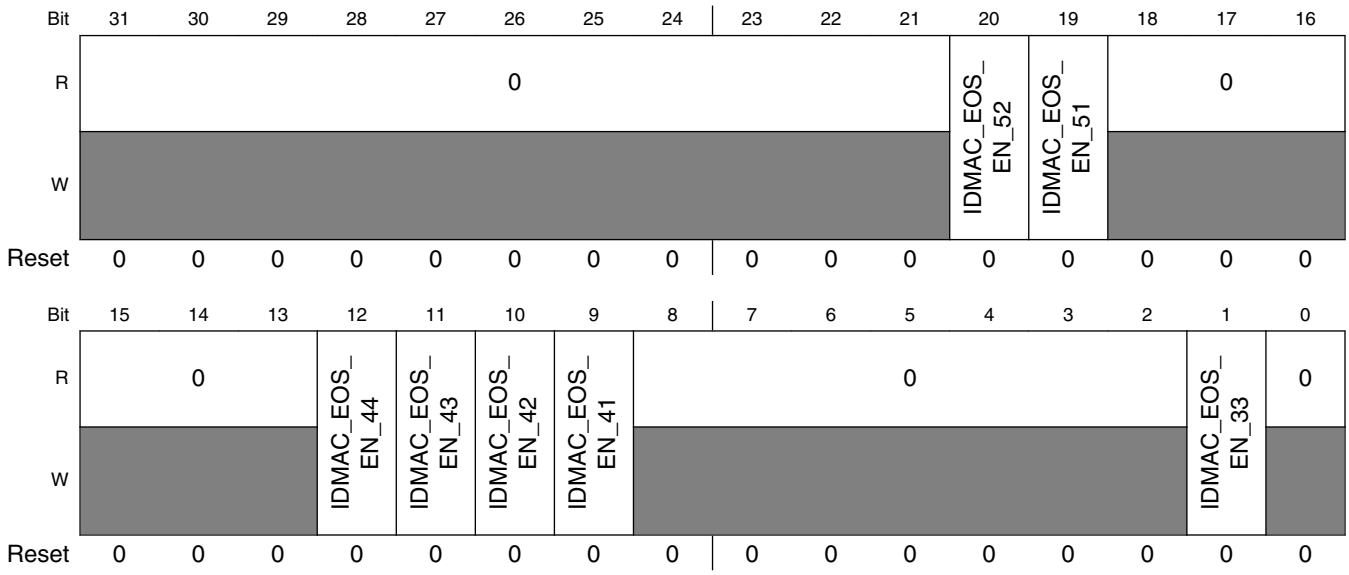
27 IDMAC_EOS_EN_27	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
26 IDMAC_EOS_EN_26	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IDMAC_EOS_EN_25	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
24 IDMAC_EOS_EN_24	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
23 IDMAC_EOS_EN_23	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
22–20 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
19 IDMAC_EOS_EN_19	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.

37.5.13 Interrupt Control Register 8 (IPUx_INT_CTRL_8)

This register contains part of IPU interrupts controls. The controls of the End of Scroll indication (EOS) of DMA Channels interrupts [63:32] can be found in this register.

Address: Base address + 58h offset



IPUx_INT_CTRL_8 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
20 IDMAC_EOS_EN_52	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
19 IDMAC_EOS_EN_51	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
18–13 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table continues on the next page...

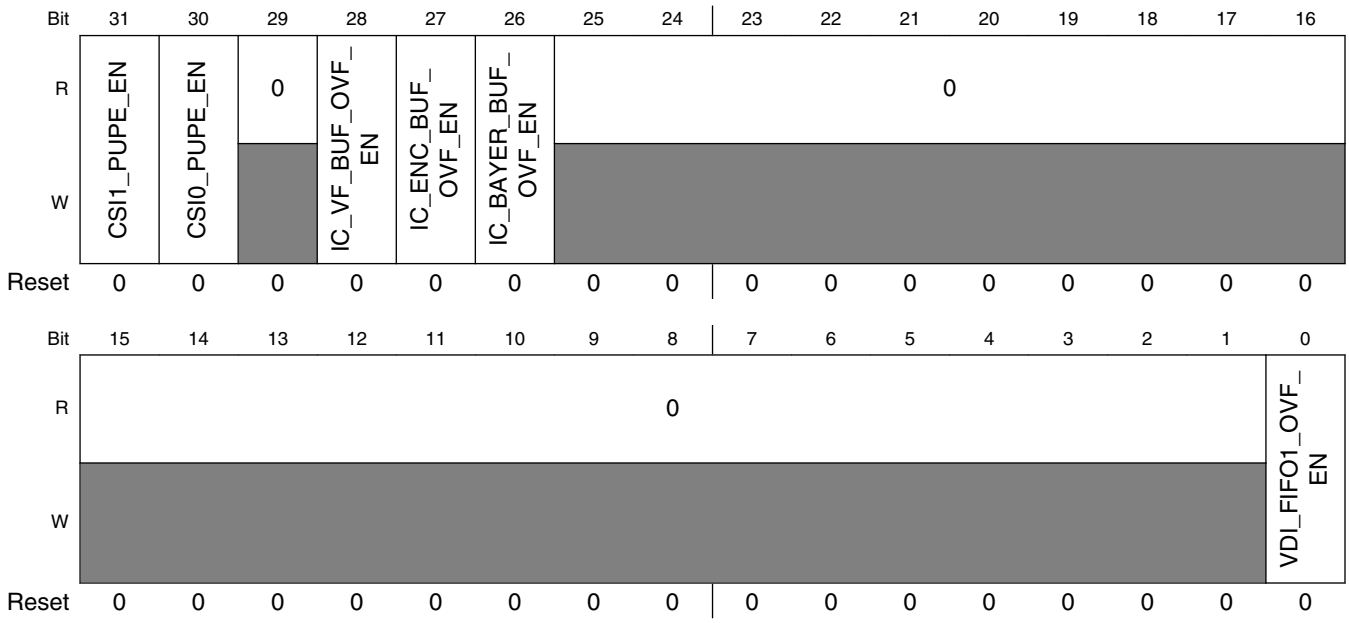
IPUx_INT_CTRL_8 field descriptions (continued)

Field	Description
12 IDMAC_EOS_EN_44	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 IDMAC_EOS_EN_43	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IDMAC_EOS_EN_42	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
9 IDMAC_EOS_EN_41	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
8–2 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 IDMAC_EOS_EN_33	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.

37.5.14 Interrupt Control Register 9 (IPUx_INT_CTRL_9)

This register contains part of IPU interrupts controls. This register controls error interrupt signals coming from different sub-blocks within

Address: Base address + 5Ch offset



IPUx_INT_CTRL_9 field descriptions

Field	Description
31 CSI1_PUPE_EN	CSI1_PUPE_EN - CSI1 parameters update error interrupt enable. This bit enables an interrupt that is a result of an error generated by the CSI1. The error is generated in case where new frame arrived from the CSI1 before the completion of the CSI1's parameters update by the SRM 0 Interrupt is disabled. 1 Interrupt is enabled.
30 CSI0_PUPE_EN	CSI0_PUPE_EN - CSI0 parameters update error interrupt enable. This bit enables an interrupt that is a result of an error generated by the CSI0. The error is generated in case where new frame arrived from the CSI0 before the completion of the CSI0's parameters update by the SRM 0 Interrupt is disabled. 1 Interrupt is enabled.
29 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

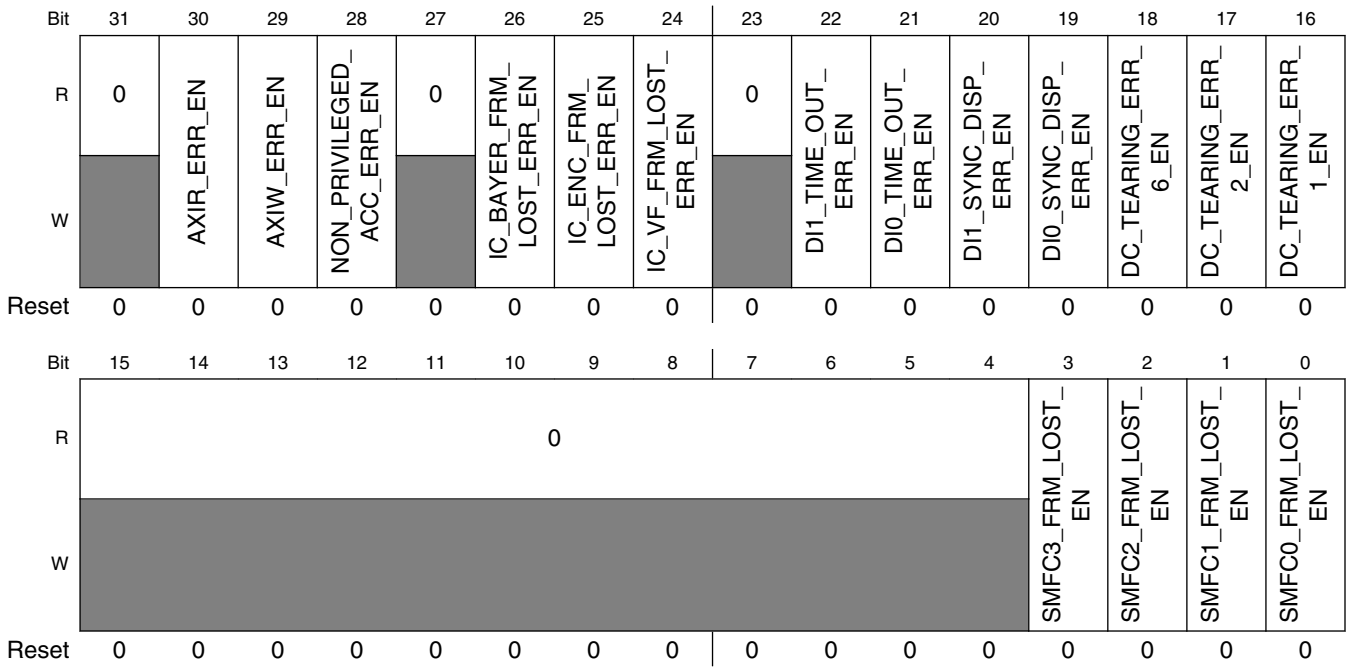
IPUx_INT_CTRL_9 field descriptions (continued)

Field	Description
28 IC_VF_BUF_ OVF_EN	This bit enables an interrupt that is a result of the IC Buffer overflow for view finder coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is disabled. 1 Interrupt is enabled.
27 IC_ENC_BUF_ OVF_EN	This bit enables an interrupt that is a result of the IC Buffer overflow for encoding coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is disabled. 1 Interrupt is enabled.
26 IC_BAYER_ BUF_OVF_EN	This bit enables an interrupt that is a result of the IC Buffer overflow for bayer coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is disabled. 1 Interrupt is enabled.
25–1 Reserved	This read-only field is reserved and always has the value 0.
0 VDI_FIFO1_ OVF_EN	FIFO1 overflow Interrupt1 Enable The VDIC generates FIFO1 overflow interrupt1 when the write pointer of FIFO1 overruns read pointer. 0 Interrupt is disabled. 1 Interrupt is enabled.

37.5.15 Interrupt Control Register 10 (IPUx_INT_CTRL_10)

This register contains part of IPU interrupts controls. This register controls error interrupt signals coming from different modules within

Address: Base address + 60h offset



IPUx_INT_CTRL_10 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 AXIR_ERR_EN	This bit enables an interrupt that is a result of AXI read access resulted with error response. 0 Interrupt is disabled. 1 Interrupt is enabled.
29 AXIW_ERR_EN	This bit enables an interrupt that is a result of AXI write access resulted with error response. 0 Interrupt is disabled. 1 Interrupt is enabled.
28 NON_PRIVILEGED_ACC_ERR_EN	Non Privileged Access Error interrupt enable. The CPMEM and the DP can be accessed by the ARM platform in privileged mode only HPROT[1] =1. An attempt to access these regions in user mode will issue an interrupt. This bit enables the interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table continues on the next page...

IPUx_INT_CTRL_10 field descriptions (continued)

Field	Description
27 Reserved	This read-only field is reserved and always has the value 0.
26 IC_BAYER_ FRM_LOST_ ERR_EN	This bit enables an interrupt that is a result of IC's Bayer frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IC_ENC_FRM_ LOST_ERR_EN	This bit enables an interrupt that is a result of IC's encoding frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
24 IC_VF_FRM_ LOST_ERR_EN	This bit enables an interrupt that is a result of IC's view finder frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
23 Reserved	This read-only field is reserved and always has the value 0.
22 DI1_TIME_OUT_ ERR_EN	DI1 time out error interrupt enable This bit enables the interrupt that is a result of a time out error during a read access via DI1 0 Interrupt is disabled. 1 Interrupt is enabled.
21 DI0_TIME_OUT_ ERR_EN	DI0 time outwore interrupt enable This bit enables the interrupt that is a result of a time out error during a read access via DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
20 DI1_SYNC_ DISP_ERR_EN	DI1 Synchronous display error enable This bit enables the interrupt that is a result of an error during access to a synchronous display via DI1 0 Interrupt is disabled. 1 Interrupt is enabled.
19 DI0_SYNC_ DISP_ERR_EN	DI0 Synchronous display error enable This bit enables the interrupt that is a result of an error during access to a synchronous display via DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
18 DC_TEARING_ ERR_6_EN	Tearing Error #6 enable This bit enables the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 6 0 Interrupt is disabled. 1 Interrupt is enabled.
17 DC_TEARING_ ERR_2_EN	Tearing Error #2 enable This bit enables the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 2

Table continues on the next page...

IPUx_INT_CTRL_10 field descriptions (continued)

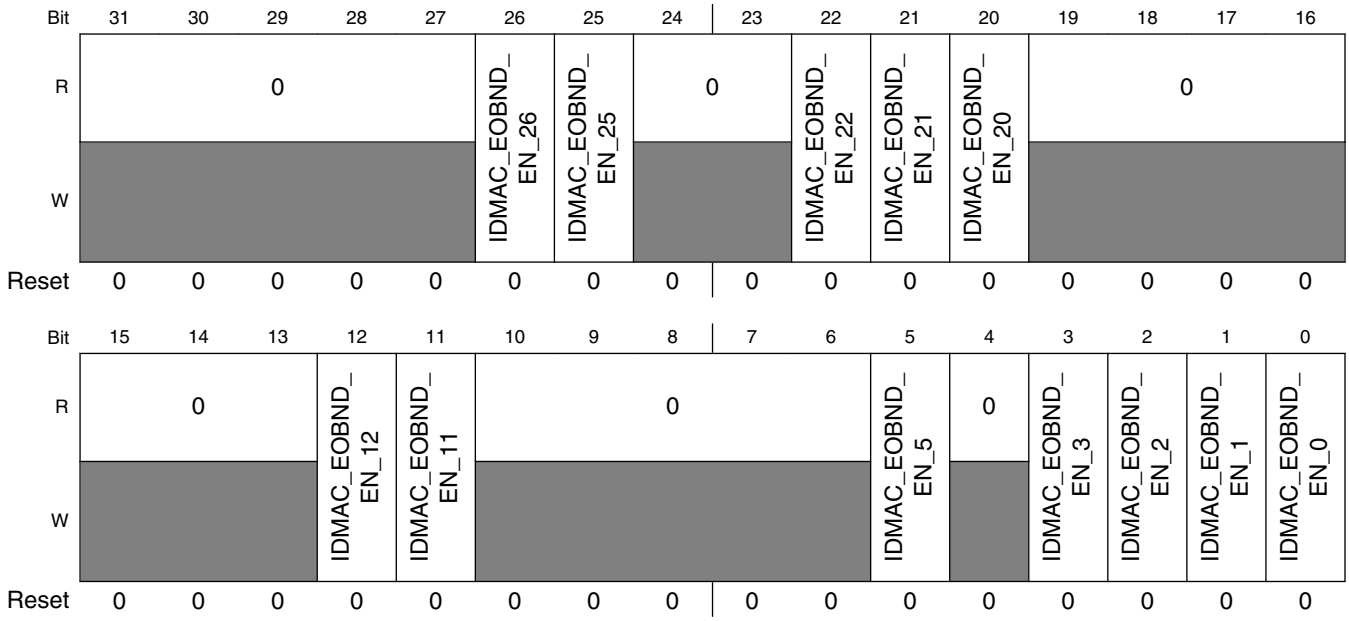
Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
16 DC_TEARING_ERR_1_EN	Tearing Error #1 enable This bit enables the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 1 0 Interrupt is disabled. 1 Interrupt is enabled.
15–4 Reserved	This read-only field is reserved and always has the value 0.
3 SMFC3_FRM_LOST_EN	Frame Lost of SMFC channel 3 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 3. 0 Interrupt is disabled. 1 Interrupt is enabled.
2 SMFC2_FRM_LOST_EN	Frame Lost of SMFC channel 2 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 2. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 SMFC1_FRM_LOST_EN	Frame Lost of SMFC channel 1 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 1. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 SMFC0_FRM_LOST_EN	Frame Lost of SMFC channel 0 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 0. 0 Interrupt is disabled. 1 Interrupt is enabled.

37.5.16 Interrupt Control Register 11 (IPUx_INT_CTRL_11)

This register contains part of IPU interrupts controls. The controls of the end-of-band indication (EOBND) of DMA Channels interrupts [31:0] can be found in this register.

- Hide VDOA_SYNC for all versions
- Show VDOA_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.

Address: Base address + 64h offset



IPUx_INT_CTRL_11 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
26 IDMAC_EOBND_EN_26	end-of-band indication of Channel interrupt. This bit is the control of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IDMAC_EOBND_EN_25	end-of-band indication of Channel interrupt. This bit is the control of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
24–23 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
22 IDMAC_EOBND_EN_22	end-of-band indication of Channel interrupt. This bit is the control of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
21 IDMAC_EOBND_EN_21	end-of-band indication of Channel interrupt. This bit is the control of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number.

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
28 DI0_CNT_EN_PRE_10_EN	This bit enables the interrupt that is a result of a trigger generated by counter #10 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
27 DI0_CNT_EN_PRE_9_EN	This bit enables the interrupt that is a result of a trigger generated by counter #9 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
26 DI0_CNT_EN_PRE_8_EN	This bit enables the interrupt that is a result of a trigger generated by counter #8 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
25 DI0_CNT_EN_PRE_7_EN	This bit enables the interrupt that is a result of a trigger generated by counter #7 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
24 DI0_CNT_EN_PRE_6_EN	This bit enables the interrupt that is a result of a trigger generated by counter #6 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
23 DI0_CNT_EN_PRE_5_EN	This bit enables the interrupt that is a result of a trigger generated by counter #5 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
22 DI0_CNT_EN_PRE_4_EN	This bit enables the interrupt that is a result of a trigger generated by counter #4 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
21 DI0_CNT_EN_PRE_3_EN	This bit enables the interrupt that is a result of a trigger generated by counter #3 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
20 DI0_CNT_EN_PRE_2_EN	This bit enables the interrupt that is a result of a trigger generated by counter #2 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
19 DI0_CNT_EN_PRE_1_EN	This bit enables the interrupt that is a result of a trigger generated by counter #1 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
18 DI0_CNT_EN_PRE_0_EN	This bit enables the interrupt that is a result of a trigger generated by counter #0 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
17 DC_ASYNC_STOP_EN	This bit enables the interrupt asserted anytime the DP stops an async flow and moves to a sync flow

Table continues on the next page...

IPUx_INT_CTRL_15 field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
16 DC_DP_START_EN	This bit enables the interrupt asserted anytime the DP start a new sync or async flow or when an async flow is interrupted by a sync flow 0 Interrupt is disabled. 1 Interrupt is enabled.
15 DI_VSYNC_PRE_1_EN	This bit enables the DI1 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is disabled. 1 Interrupt is enabled.
14 DI_VSYNC_PRE_0_EN	This bit enables the DI0 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is disabled. 1 Interrupt is enabled.
13 DC_FC_6_EN	This bit enables the DC Frame Complete on channel #6 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
12 DC_FC_4_EN	This bit enables the DC Frame Complete on channel #4 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
11 DC_FC_3_EN	This bit enables the DC Frame Complete on channel #3 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
10 DC_FC_2_EN	This bit enables the DC Frame Complete on channel #2 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
9 DC_FC_1_EN	This bit enables they'd Frame Complete on channel #1 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
8 DC_FC_0_EN	This bit enables they'd Frame Complete on channel #0 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
7 DP_ASF_BRAKE_EN	DP Async Flow Brake enable bit. This bit enables the interrupt that is a result of the async flow brake at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
6 DP_SF_BRAKE_EN	DP Sync Flow Brake enable bit. This bit enables the interrupt that is a result of the Sync flow brake at the DP

Table continues on the next page...

IPUx_INT_CTRL_15 field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
5 DP_ASF_END_EN	DP Async Flow End enable bit. This bit enables the interrupt that is a result of the Async flow end at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
4 DP_ASF_START_EN	DP Async Flow Start enable bit. This bit enables the interrupt that is a result of the Async flow start at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
3 DP_SF_END_EN	DP Sync Flow End enable bit. This bit enables the interrupt that is a result of the Sync flow end at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
2 DP_SF_START_EN	DP Sync Flow Start enable bit. This bit enables the interrupt that is a result of the Sync flow start at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
1 SNOOPING2_INT_EN	IPU snooping 2 interrupt enable bit. This bit enables the interrupt that is a result of the detection of a snooping 2 signal assertion coming to the IPU 0 Interrupt is disabled. 1 Interrupt is enabled.
0 SNOOPING1_INT_EN	IPU snooping 1 interrupt enable bit. This bit enables the interrupt that is a result of the detection of a snooping 1 signal assertion coming to the IPU 0 Interrupt is disabled. 1 Interrupt is enabled.

37.5.21 SDMA Event Control Register 1 (IPUx_SDMA_EVENT_1)

This register contains part of IPU SDMA events controls. The controls of EOF (end of frame) of DMA Channels SDMA events [31:0] can be found in this register.

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value 0. 0 SDMA event is disabled. 1 SDMA event is enabled.
20 IDMAC_EOF_SDMA_EN_52	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
19 IDMAC_EOF_SDMA_EN_51	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
18 IDMAC_EOF_SDMA_EN_50	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

IPUx_SDMA_EVENT_2 field descriptions (continued)

Field	Description
	0 SDMA event is disabled. 1 SDMA event is enabled.
17 IDMAC_EOF_ SDMA_EN_49	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
16 IDMAC_EOF_ SDMA_EN_48	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
15 IDMAC_EOF_ SDMA_EN_47	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
14 IDMAC_EOF_ SDMA_EN_46	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
13 IDMAC_EOF_ SDMA_EN_45	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
12 IDMAC_EOF_ SDMA_EN_44	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
11 IDMAC_EOF_ SDMA_EN_43	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
10 IDMAC_EOF_ SDMA_EN_42	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
9 IDMAC_EOF_ SDMA_EN_41	Enable End of Frame of Channel SDMA event. This bit is the control of End Of Frame of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

Field	Description
10 IDMAC_TH_ SDMA_EN_42	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
9 IDMAC_TH_ SDMA_EN_41	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
8 IDMAC_TH_ SDMA_EN_40	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
7–2 Reserved	This read-only field is reserved and always has the value 0. 0 SDMA event is disabled. 1 SDMA event is enabled.
1 IDMAC_TH_ SDMA_EN_33	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
0 Reserved	This read-only field is reserved and always has the value 0. 0 SDMA event is disabled. 1 SDMA event is enabled.

37.5.31 Shadow Registers Memory Priority 1 Register (IPUx_SRM_PRI1)

The register controls the priority of SRM updates. The priority level for each block that has a shadow of its registers in the SRM should be unique. The priority level defines the order of SRM updates. A block with priority set to 010 will be updated before a block with priority set to 001.

Address: Base address + A0h offset

IPUx_SRM_PRI1 field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12–11 CSI0_SRM_MODE	CSI0 SRM Mode This field controls the SRM logic that handles the CSI0 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the CSI1's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM Platform. The Register will be update now
10–8 CSI0_SRM_PRI	CSI0 SRM priority This bits define the priority of the CSI1 block
7–5 Reserved	This read-only field is reserved and always has the value 0.
4–3 CSI1_SRM_MODE	CSI1 SRM Mode This field controls the SRM logic that handles the CSI1 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the CSI0's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
CSI1_SRM_PRI	CSI1 SRM priority This bits define the priority of the CSI0 module

37.5.32 Shadow Registers Memory Priority 2 Register (IPUx_SRM_PRI2)

The register controls the priority of SRM updates. The priority level for each block that has a shadow of its registers in the SRM should be unique. The priority level defines the order of SRM updates. a block with priority set to 010 will be updated before a block with priority set to 001.

IPUx_SRM_PRI2 field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28–27 DI1_SRM_MODE	DCI1 SRM Mode This field controls the SRM logic that handles the DI1 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DI1 region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
26–24 DI1_SRM_PRI	DI1 SRM priority This bits define the priority of the DI1 module
23–21 Reserved	This read-only field is reserved and always has the value 0.
20–19 DI0_SRM_MCU_USE	DI0 SRM is used by ARM platform This bit indicates that the registers of the DI0 are currently being updated by the ARM platform. The ARM platform should set this bit before accessing the SRM part that is relevant to the DI0. The ARM platform should clear this bit when the update procedure is finished. When this bit is set the SRM mechanism will not update the DI0's registers to avoid data coherency problems. 1 DI0 SRM is currently updated by the ARM platform 0 DI0 SRM s currently not updated by the ARM platform
18–16 DI0_SRM_PRI	DI0 SRM priority This bits define the priority of the DI0 module

Table continues on the next page...

IPUx_SRM_PRI2 field descriptions (continued)

Field	Description
15–14 DC_6_SRM_MODE	DC Group #6 SRM Mode This field controls the SRM logic that handles the DC Group #6 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DC Group #6's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
13–12 DC_2_SRM_MODE	DC Group #2 SRM Mode This field controls the SRM logic that handles the DC Group #2 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DC Group #2's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
11–9 DC_SRM_PRI	DC SRM priority This bits define the priority of the DC module
8–7 DP_A1_SRM_MODE	DP Async flow #1 SRM Mode This field controls the SRM logic that handles the DP Async flow #1 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DP Async flow #1 region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
6–5 DP_A0_SRM_MODE	DP Async flow #0 SRM Mode This field controls the SRM logic that handles the DP Async flow #0 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DP Async flow #0 region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
4–3 DP_S_SRM_MODE	DP sync flow SRM Mode This field controls the SRM logic that handles the DP sync flow registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DP sync flow region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done on the next frame. 10 Reserved 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
DP_SRM_PRI	DP SRM priority This bits define the priority of the DP module

37.5.33 FSU Processing Flow 1 Register (IPUx_FS_PROC_FLOW1)

This register contain controls for IPU's tasks.

Address: Base address + A8h offset

37.5.35 FSU Processing Flow 3 Register (IPUx_FS_PROC_FLOW3)

This register contains controls for IPU's tasks.

- Hide VPU_SUB_FRAME_SYNC for all versions
- Show VPU_SUB_FRAME_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.
- This requires some sophisticated conditional tag settings

37.5.38 SKIP Register (IPUx_SKIP)

This register controls the different frame skipping supported by the IPU.

Address: Base address + BCh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VDI_SKIP												VDI_MAX_ RATIO_SKIP				CSI_SKIP_IC_VF					CSI_ MAX_ RATIO_ SKIP_IC_ VF			CSI_SKIP_IC_ ENC					CSI_ MAX_ RATIO_ SKIP_IC_ ENC		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPUx_SKIP field descriptions

Field	Description
31–20 VDI_SKIP	VDI_SKIP These 12 bits define the skipping pattern of the frames send from the VDIC. The VDIC avoids reading fields from the memory if the output frame is skipped. Skipping is relevant only if the source to the VDIC is coming from the CSI. Skipping is done for a set of frames. The number of frames in a set is defined at VDI_MAX_RATIO_SKIP. when VDI_MAX_RATIO_SKIP = 1 => VDI_SKIP[1:0] is used; other bits are ignored when VDI_MAX_RATIO_SKIP = 2 => VDI_SKIP[2:0] are used; other bits are ignored .. .. when VDI_MAX_RATIO_SKIP = 11 => VDI_SKIP[11:0] are used;
19–16 VDI_MAX_ RATIO_SKIP	Maximum Ratio Skip for VDIC

Table continues on the next page...

IPUx_SKIP field descriptions (continued)

Field	Description
	These bits define the number of frames in a skipping set. The maximum value of this bits is 11. When set to 0 the skipping is disabled.
15–11 CSI_SKIP_IC_VF	CSI SKIP IC_VF These 5 bits define the skipping pattern of the frames send to the IC for view finder task from one of the CSIs as defined on the CSI_SEL and IC_INPUT bits Skipping is done for a set of frames. The number of frames in a set is defined at CSI_MAX_RATIO_SKIP_IC_VF. when CSI_MAX_RATIO_SKIP_IC_VF = 1 => CSI_SKIP_IC_VF[1:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF = 2 => CSI_SKIP_IC_VF[2:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF =3 => CSI_SKIP_IC_VF[3:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF = 4 => CSI_SKIP_IC_VF[4:0] are used; Setting bit #n of CSI_SKIP_IC_VF means that the #n frame in the set is skipped. For example: if CSI_MAX_RATIO_SKIP_IC_VF = 4 and CSI_SKIP_IC_VF = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI_MAX_RATIO_SKIP_IC_VF is set to 4
10–8 CSI_MAX_ RATIO_SKIP_ IC_VF	CSI Maximum Ratio Skip for IC (view finder task) These bits define the number of frames in a skipping set. The maximum value of this bits is 4. When set to 0 the skipping is disabled.
7–3 CSI_SKIP_IC_ ENC	CSI SKIP IC_ENC These 5 bits define the skipping pattern of the frames send to the IC for encoding task from one of the CSIs as defined on the CSI_SEL and IC_INPUT bits Skipping is done for a set of frames. The number of frames in a set is defined at CSI_MAX_RATIO_SKIP_IC_ENC. when CSI_MAX_RATIO_SKIP_IC_ENC = 1 => CSI_SKIP_IC_ENC[1:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 2 => CSI_SKIP_IC_ENC[2:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 3 => CSI_SKIP_IC_ENC[3:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 4 => CSI_SKIP_IC_ENC[4:0] are used; Setting bit #n of CSI_SKIP_IC_ENC means that the #n frame in the set is skipped. For example: if CSI_MAX_RATIO_SKIP_IC_ENC = 4 and CSI_SKIP_IC_ENC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI_MAX_RATIO_SKIP_IC_ENC is set to 4
CSI_MAX_ RATIO_SKIP_ IC_ENC	CSI Maximum Ratio Skip for IC (encoding task) These bits define the number of frames in a skipping set. The maximum value of this bits is 4. When set to 0 the skipping is disabled.

37.5.39 Display Alternate Configuration Register (IPUx_DISP_ALT_CONF)

This register controls various parameters that are used for alternate flows related to the display modules.

Address: Base address + C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

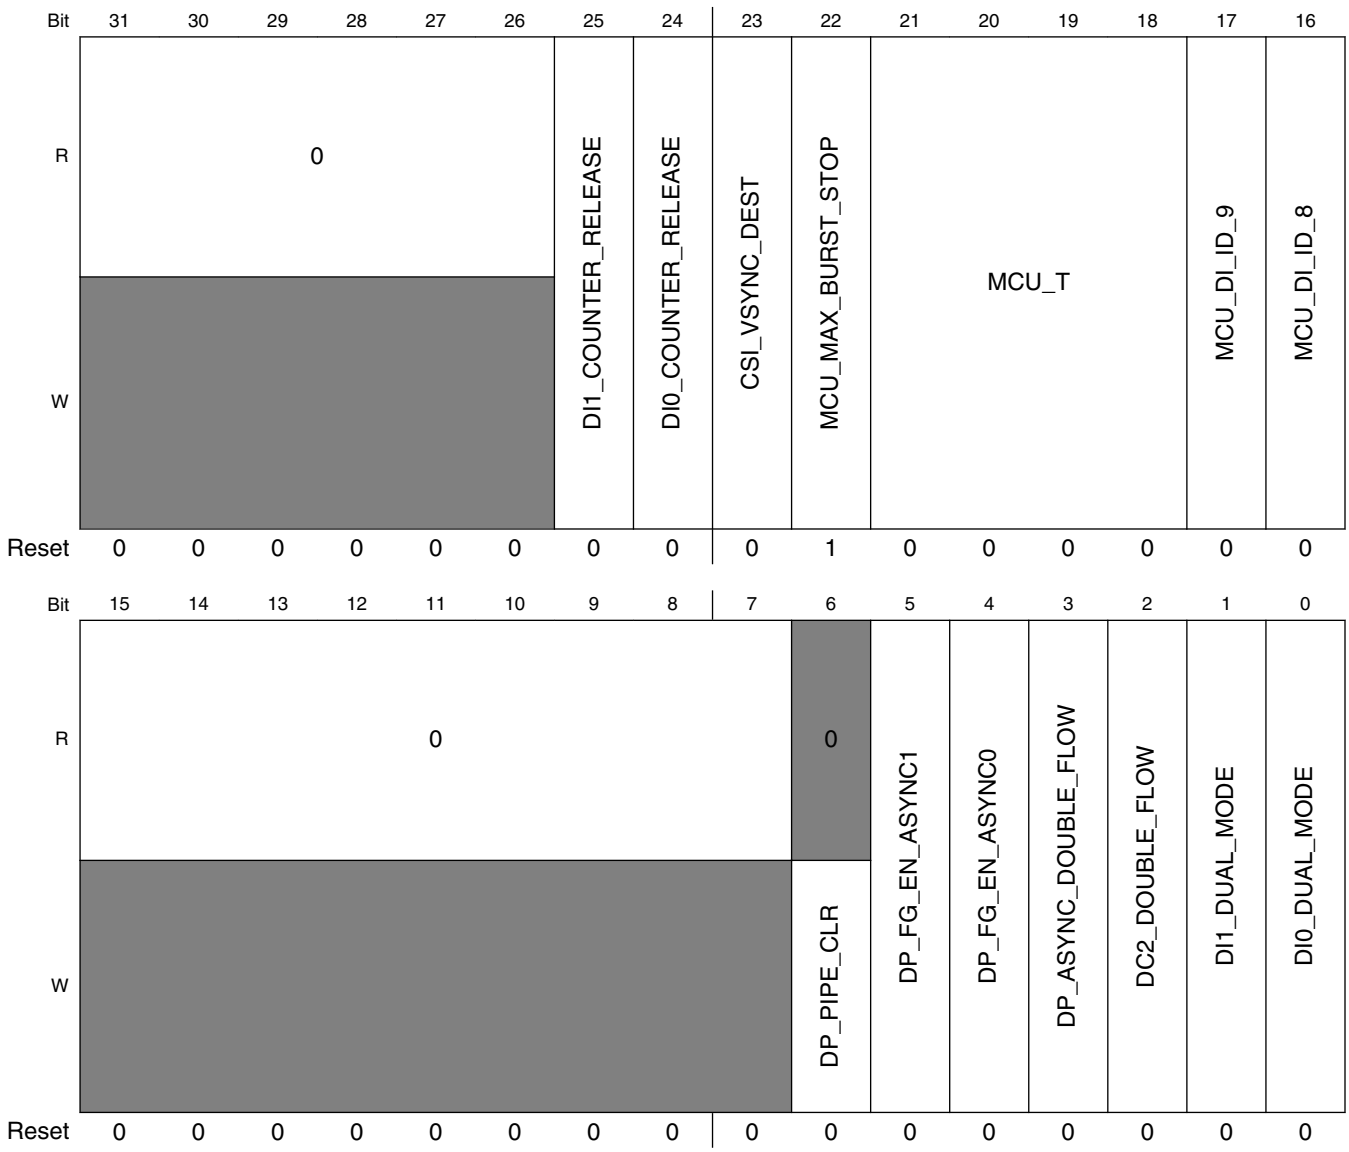
IPUx_DISP_ALT_CONF field descriptions

Field	Description
Reserved	This read-only field is reserved and always has the value 0.

37.5.39 Display General Control Register (IPUx_DISP_GEN)

This register controls various aspects of the display port.

Address: Base address + C4h offset



IPUx_DISP_GEN field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

IPUx_DISP_GEN field descriptions (continued)

Field	Description
25 DI1_COUNTER_RELEASE	DI1 Counter release By default the DI0 counters responsible for waveform generation for sync flow are frozen. For the first attempt to use the DI in sync flow the user should set this bit 1 counter is released and running 0 counter is cleared and stopped
24 DI0_COUNTER_RELEASE	DI1 Counter release By default the DI0 counters responsible for waveform generation for sync flow are frozen. For the first attempt to use the DI in sync flow the user should set this bit 1 counter is released and running 0 counter is cleared and stopped
23 CSI_VSYNC_DEST	CSI_VSYNC destination This bit defines the destination of the VSYNC coming from the CSI's 1 csi1_vsync is connected to DI0; csi0_vsync is connected to DI1 0 csi0_vsync is connected to DI0; csi1_vsync is connected to DI1
22 MCU_MAX_BURST_STOP	ARM platform Maximal burst This bit limit the maximal unspecified length burst. 1 The maximum unspecified burst length is 8-beat 0 The unspecified burst length is unlimited
21–18 MCU_T	The address space for accesses through the AHB-lite slave port is MB and it is split internally (with 32MB resolution) according to bits [28:25] of the address. Using the following notation: Address = (ID[31:29], MSB[28:25], LSB[24:0]) The address is used as follows ("T" is a configurable integer between 0 and 13): MSB<T: access to an external device, with address = (MSB, LSB) T<=MSB<14: access to an external device, with address (MSB-T, LSB)
17 MCU_DI_ID_9	MCU_DI_ID_9 - DI ID via DC channel 9. This bit defines the DI that the ARM platform DC's access via channel #9 1 ARM platform accesses DC's channel #9 via DI1. 0 ARM platform accesses DC's channel #9 via DI0.
16 MCU_DI_ID_8	MCU_DI_ID_8 - DI ID via DC channel 8. This bit defines the DI that the ARM platform DC's access via channel #8 1 ARM platform accesses DC's channel #8 via DI1. 0 ARM platform accesses DC's channel #8 via DI0.
15–7 Reserved	This read-only field is reserved and always has the value 0.
6 DP_PIPE_CLR	DP Pipe Clear This bit clears the internal pipe of the DP. The user may use this bit in case of an error condition This is a self clear bit

Table continues on the next page...

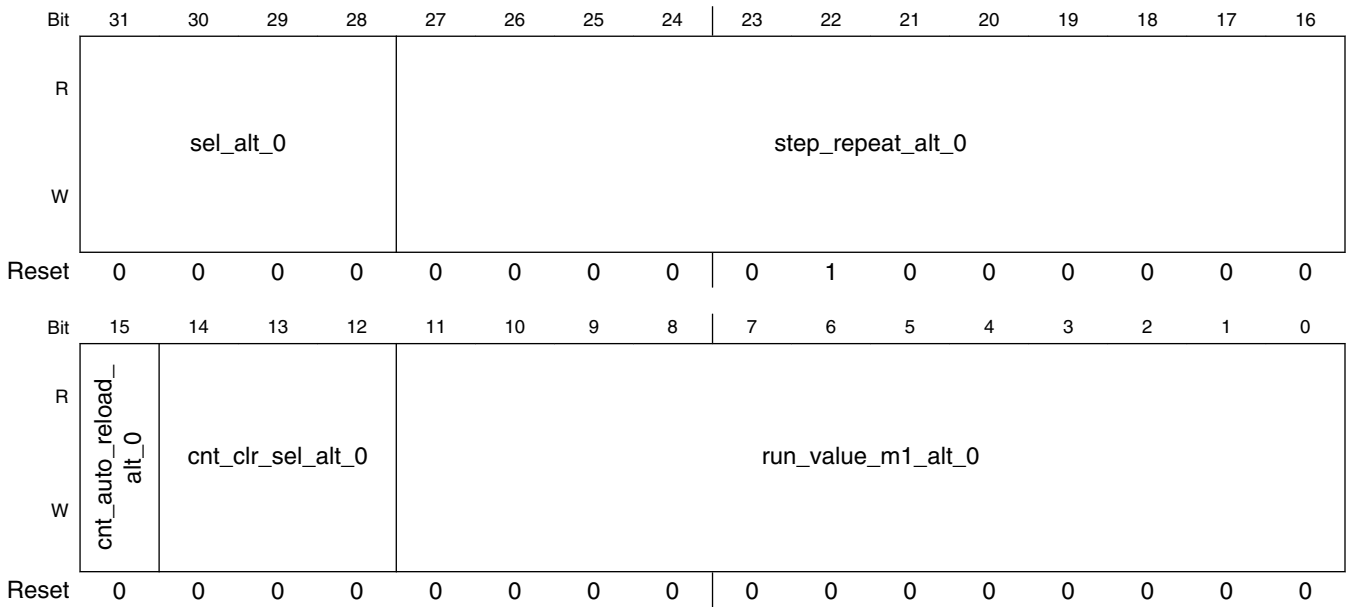
IPUx_DISP_GEN field descriptions (continued)

Field	Description
	1 Clear the internal pipe of the DP 0 Idle - does nothing
5 DP_FG_EN_ASYNC1	FG_EN - partial plane Enable for async flow 1. This bit enables the partial plane channel. 1 partial plane channel is enabled. 0 partial plane channel is disabled.
4 DP_FG_EN_ASYNC0	FG_EN - partial plane Enable for async flow 0. This bit enables the partial plane channel. 1 partial plane channel is enabled. 0 partial plane channel is disabled.
3 DP_ASYNC_DOUBLE_FLOW	DP Async Double Flow. This bit define how many async flows are currently handles via DP channel (ch24+29) 1 2 flows are handled via DP 0 single flow is handled via DP
2 DC2_DOUBLE_FLOW	DC2 Double Flow. This bit define how many flows are currently handles via DC2 channel (ch41) 1 2 flows are handled via DC2 0 single flow is handled via DC2
1 DI1_DUAL_MODE	DI1 dual mode control 1 DI1 operates in dual mode 0 DI1 is not in dual mode
0 DI0_DUAL_MODE	DI0 dual mode control 1 DI0 operates in dual mode 0 DI0 is not in dual mode

37.5.40 Display Alternate Flow Control Register 1 (IPUx_DISP_ALT1)

This register controls various aspects of the display port.

Address: Base address + C8h offset



IPUx_DISP_ALT1 field descriptions

Field	Description
31–28 sel_alt_0	Select alternative parameters instead of DI Sync Wave Gen counter#. The DI is selected according to DP's synchronous channel destination 0000-disable 0001 instead of counter 1 0010 instead of counter 2 1000 instead of counter 8
27–16 step_repeat_alt_0	This fields defines the amount of repetitions that will be performed by the counter
15 cnt_auto_reload_alt_0	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the step_repeat_alt_0 field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the step_repeat_alt_0 field
14–12 cnt_clr_sel_alt_0	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock.

Table continues on the next page...

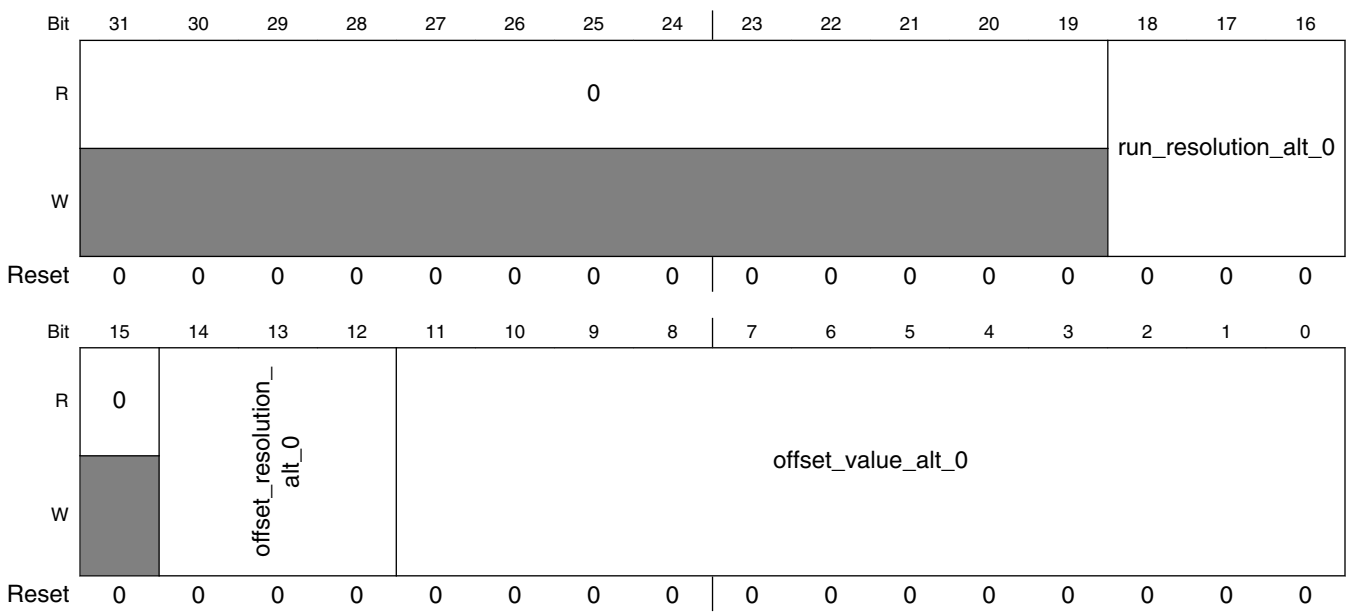
IPUx_DISP_ALT1 field descriptions (continued)

Field	Description
	010 Reserved 011 Reserved 100 Reserved 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
run_value_m1_alt_0	Counter pre defined value This fields defines the counter pre defines value. real value- 1

37.5.41 Display Alternate Flow Control Register 2 (IPUx_DISP_ALT2)

This register controls various aspects of the display port.

Address: Base address + CCh offset



IPUx_DISP_ALT2 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

IPUx_DISP_ALT2 field descriptions (continued)

Field	Description
18–16 run_resolution_alt_0	Counter Run Resolution This field defines the trigger causing the counter to increment. The counter run resolution should be defined in the same way as in original DI's counter#
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 offset_resolution_alt_0	Counter offset Resolution This field defines the trigger causing the offset counter to increment The counter offset resolution should be defined in the same way as in original DI's counter#
offset_value_alt_0	Counter offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by

37.5.42 Display Alternate Flow Control Register 3 (IPUx_DISP_ALT3)

This register controls various aspects of the display port.

Address: Base address + D0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

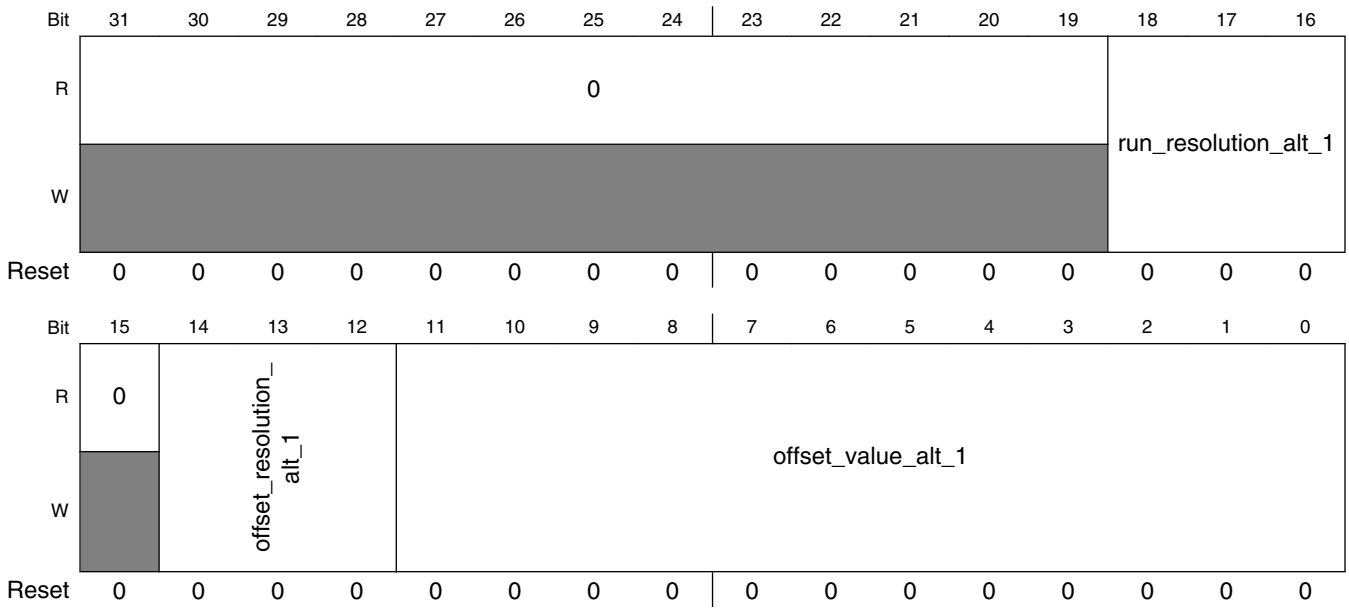
37.5.43 Display Alternate Flow Control Register 4 (IPUx_DISP_ALT4)

This register controls various aspects of the display port.

Address: Base address + D4h offset



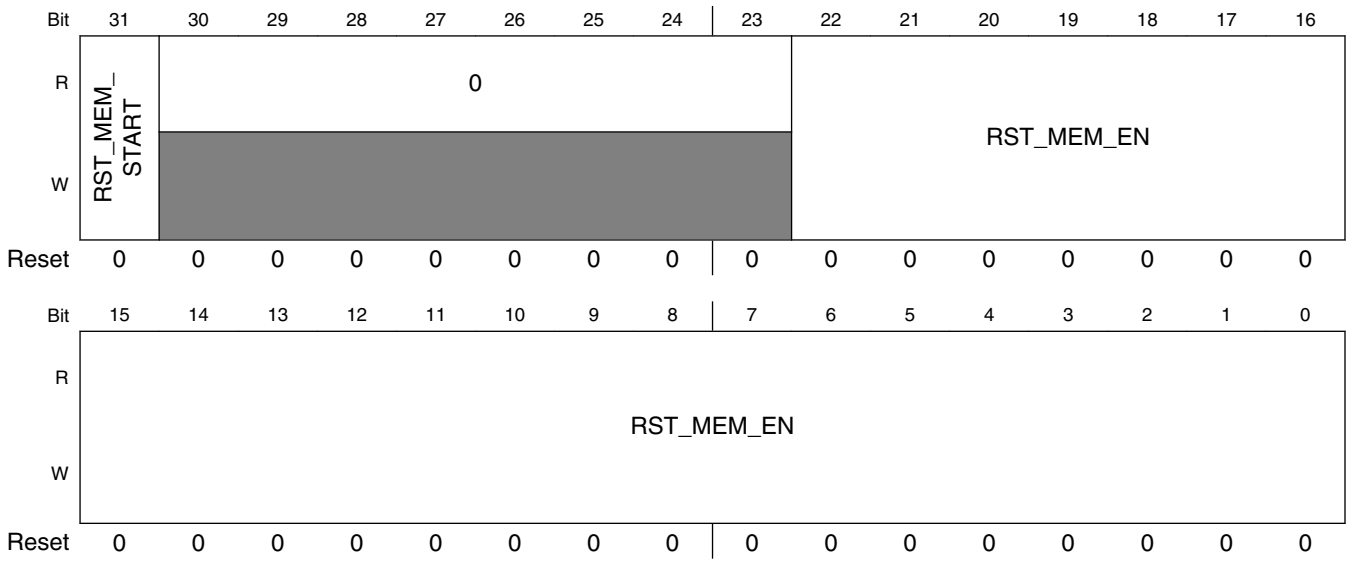
IPUx_DISP_ALT4 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value 0.
18–16 run_resolution_alt_1	Counter Run Resolution This field defines the trigger causing the counter to increment. The counter run resolution should be defined in the same way as in original DI's counter#
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 offset_resolution_alt_1	Counter offset Resolution This field defines the trigger causing the offset counter to increment The counter offset resolution should be defined in the same way as in original DI's counter#
offset_value_alt_1	Counter offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by

37.5.44 Memory Reset Control Register (IPUx_MEM_RST)

This register controls the memory reset mechanism. IPU has a hardware mechanism for clearing the content of the internal memories. This allows the user to clear the content of or more of the internal memories without the need to perform write accesses to the memories.

Address: Base address + DCh offset



IPUx_MEM_RST field descriptions

Field	Description
31 RST_MEM_START	Memory Reset Start Writing one to this bit activate the memory reset mechanism. The memories that their corresponding RST_MEM_EN bit is set will be cleared. When the memory reset mechanism completes the memory clearing procedure this bit will be automatically cleared. 1 The memory reset mechanism is activated and busy 0 Idle, the memory reset mechanism is not working.
30–23 Reserved	This read-only field is reserved and always has the value 0.
RST_MEM_EN	Reset Memory Enable Each bit on this field enables the memory reset mechanism for a specific memory. The user should set the relevant bits for the memories that need to be cleared. Below is the list of memories and their corresponding bit. srm = rst_mem_en[0] alpha = rst_mem_en[1] cpmem = rst_mem_en[2]

Table continues on the next page...

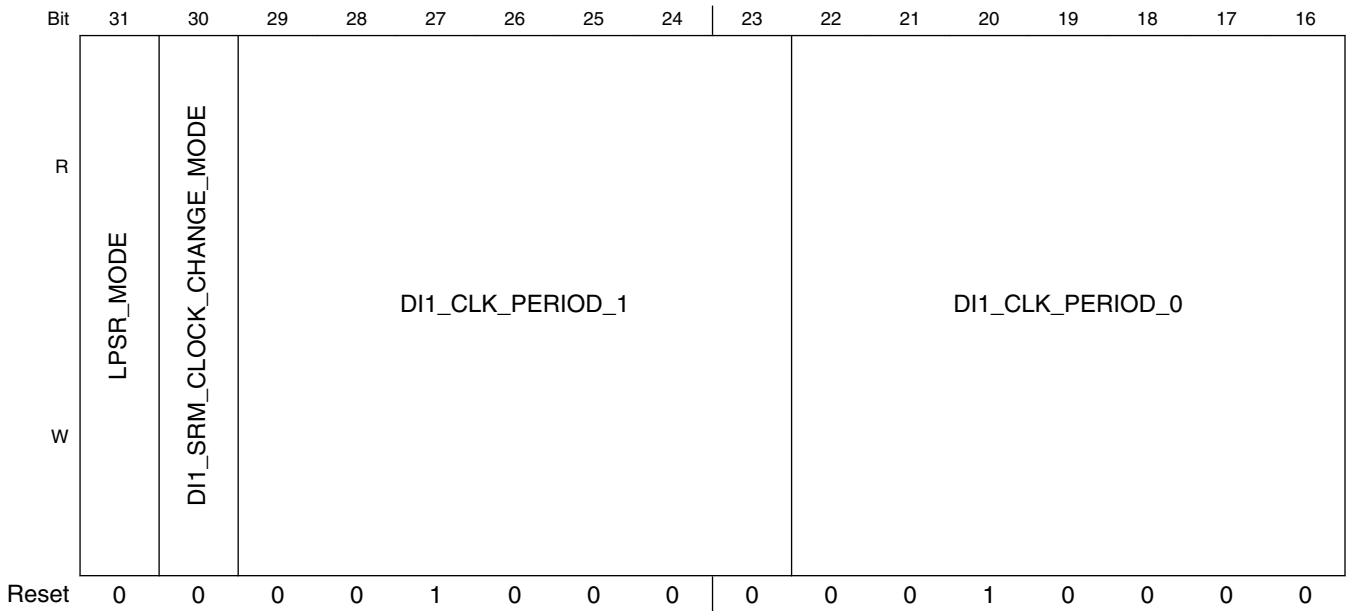
IPUx_MEM_RST field descriptions (continued)

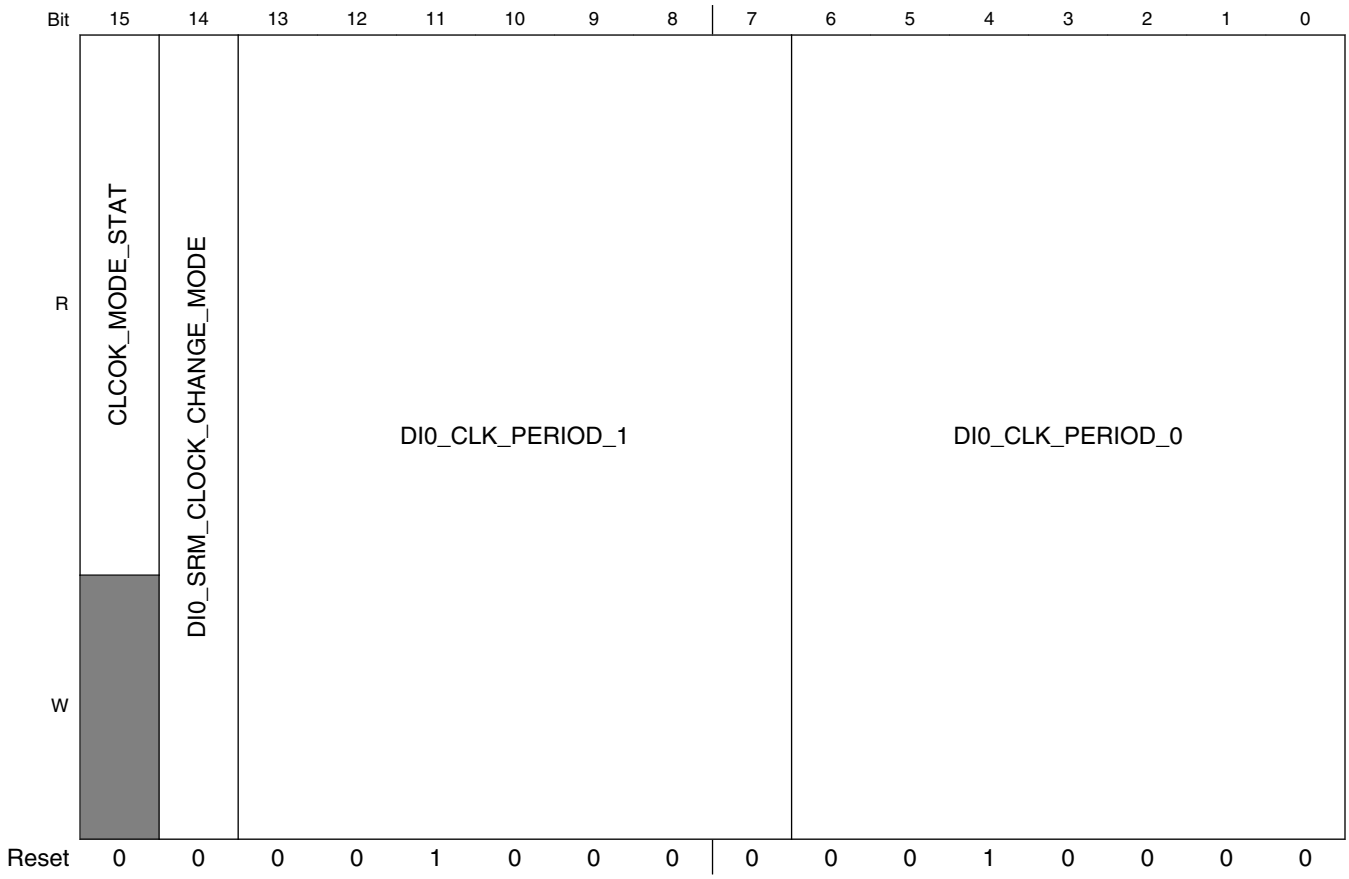
Field	Description
	tpm = rst_mem_en[3] mpm = rst_mem_en[4] bm = rst_mem_en[5] rm = rst_mem_en[6] dstm = rst_mem_en[7] dsom = rst_mem_en[8] lut0 = rst_mem_en[9] lut1 = rst_mem_en[10] ram_smfc = rst_mem_en[11] vdi_fifo2 = rst_mem_en[12] vdi_fifo3 = rst_mem_en[13] icb = rst_mem_en[14] vdi_fifo1 = rst_mem_en[15] dc_template = rst_mem_en[20] dmfc_rd = rst_mem_en[21] dmfc_wr = rst_mem_en[22]

37.5.45 Power Modes Control Register (IPUx_PM)

This register controls the automatic transitions of the IPU between different power modes of the SoC and handles the clock change modes.

Address: Base address + E0h offset





IPUx_PM field descriptions

Field	Description
31 LPSR_MODE	LPSR Mode This bit indicates that the next attempt for entering low power mode is an attempt to move to LPST mode. Setting this bit by the user is essential in order to assure proper response of the IPU to the assertion of the stop request from the CCM. 1 Next low power mode will be LPSR 0 Next low power mode is not LPSR
30 DI1_SRM_ CLOCK_ CHANGE_MODE	SRM clock change mode When the clock is going to be changed to any new ratio other then 1:1, 1:2. 1:4. The user needs to prepare an alternate set of DI setting in the SRM. This bit enable this mode. This bit is self cleared. 1 SRM clock change mode is enabled; the next clock change will be done by updating the DI settings from the SRM 0 SRM clock change mode is disabled.
29–23 DI1_CLK_ PERIOD_1	DI1_CLK period option 1. This parameter defines the period of the clock that the DI1 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI1 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed.

Table continues on the next page...

IPUx_PM field descriptions (continued)

Field	Description
	The value to be programmed to the DI1_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
22–16 DI1_CLK_ PERIOD_0	DI1_CLK period option 0. This parameter defines the period of the clock that the DI1 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI1 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI1_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
15 CLCOK_MODE_ STAT	Clock mode status This is a read only bit indicating what is the current clock mode 1 current clock mode is 1 0 current clock mode is 0
14 DI0_SRM_ CLOCK_ CHANGE_MODE	SRM clock change mode When the clock is going to be changed to any new ratio other then 1:1, 1:2. 1:4. The user needs to prepare an alternate set of DI setting in the SRM. This bit enable this mode. This bit is self cleared. 1 SRM clock change mode is enabled; the next clock change will be done by updating the DI settings from the SRM 0 SRM clock change mode is disabled.
13–7 DI0_CLK_ PERIOD_1	DI0_CLK period option 1. This parameter defines the period of the clock that the DI0 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI0 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI0_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
DI0_CLK_ PERIOD_0	DI0_CLK period option 0. This parameter defines the period of the clock that the DI0 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]).

Table continues on the next page...

IPUx_PM field descriptions (continued)

Field	Description
	Setting this value to 1.0 (default) means that the DI0 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI0_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with

37.5.46 General Purpose Register (IPUx_GPR)

The register contains general purpose bits.

Address: Base address + E4h offset

Field	Description
	0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
20 DMA_CH_DB_ MODE_SEL_52	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
19 DMA_CH_DB_ MODE_SEL_51	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
18 DMA_CH_DB_ MODE_SEL_50	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
17 DMA_CH_DB_ MODE_SEL_49	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
16 DMA_CH_DB_ MODE_SEL_48	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
15 DMA_CH_DB_ MODE_SEL_47	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
14 DMA_CH_DB_ MODE_SEL_46	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
13 DMA_CH_DB_ MODE_SEL_45	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
12 DMA_CH_DB_ MODE_SEL_44	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number.

Field	Description
9 DMA_CH_ALT_DB_MODE_SEL_41	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
8–2 Reserved	This read-only field is reserved and always has the value 0. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
1 DMA_CH_ALT_DB_MODE_SEL_33	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
0 Reserved	This read-only field is reserved and always has the value 0. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.

37.5.51 Alternate Channel Triple Buffer Mode Select 0 Register (IPUx_ALT_CH_TRB_MODE_SEL0)

The register contains triple buffer mode select control information for 32 IPU's DMA channels.

When the channel is configured for triple buffer mode. The double buffer mode settings configured on the corresponding DB_MODE_SEL bit are overridden.

- Hide VPU_SUB_FRAME_SYNC for all versions
- Show VPU_SUB_FRAME_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.
- This requires some sophisticated conditional tag settings

IPUx_INT_STAT_7 field descriptions

Field	Description
31 IDMAC_EOS_EN_31	End of Scroll indication of Channel interrupt. This bit is the status bit of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
30 Reserved	This read-only field is reserved and always has the value 0. 0 Interrupt is cleared. 1 Interrupt is requested.
29 IDMAC_EOS_EN_29	End of Scroll indication of Channel interrupt. This bit is the status bit of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
28 IDMAC_EOS_EN_28	End of Scroll indication of Channel interrupt. This bit is the status bit of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
27 IDMAC_EOS_EN_27	End of Scroll indication of Channel interrupt. This bit is the status bit of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
26 IDMAC_EOS_EN_26	End of Scroll indication of Channel interrupt. This bit is the status bit of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
25 IDMAC_EOS_EN_25	End of Scroll indication of Channel interrupt. This bit is the status bit of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
24 IDMAC_EOS_EN_24	End of Scroll indication of Channel interrupt. This bit is the status bit of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.

Table continues on the next page...

IPUx_INT_STAT_9 field descriptions

Field	Description
31 CSI1_PUPE	CSI1_PUPE - CSI1 parameters update error interrupt. This bit indicates on an interrupt that is a result of an error generated by the CSI1. The error is generated in case where new frame arrived from the CSI1 before the completion of the CSI1's parameters update by the SRM 0 Interrupt is cleared. 1 Interrupt is requested.
30 CSI0_PUPE	CSI0_PUPE - CSI0 parameters update error interrupt. This bit indicates on an interrupt that is a result of an error generated by the CSI0. The error is generated in case where new frame arrived from the CSI0 before the completion of the CSI0's parameters update by the SRM 0 Interrupt is cleared. 1 Interrupt is requested.
29 Reserved	This read-only field is reserved and always has the value 0.
28 IC_VF_BUF_OVF	This bit indicates on an interrupt that is a result of the IC Buffer overflow for view finder coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
27 IC_ENC_BUF_OVF	This bit indicates on an interrupt that is a result of the IC Buffer overflow for encoding coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
26 IC_BAYER_BUF_OVF	This bit indicates on an interrupt that is a result of the IC Buffer overflow for Bayer coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
25–1 Reserved	This read-only field is reserved and always has the value 0.
0 VDI_FIFO1_OVF	FIFO1 overflow Interrupt1 The VDIC generate FIFO1 overflow interrupt1 when write pointer of FIFO1 overrun read pointer. 0 Interrupt is cleared. 1 Interrupt is requested.

37.5.61 Interrupt Status Register 10 (IPUx_INT_STAT_10)

IPU status registers are not stored in the SRM during power gating mode.This register contains part of IPU interrupts status bits. This register holds error interrupt indications coming from different modules within All the bits in this register are write one to clear.

Address: Base address + 224h offset

IPUx_INT_STAT_10 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 AXIR_ERR	This bit indicates on an interrupt that is a result of AXI read access resulted with error response. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
29 AXIW_ERR	This bit indicates on an interrupt that is a result of AXI write access resulted with error response. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
28 NON_ PRIVILEGED_ ACC_ERR	Non Privileged Access Error interrupt. This bit indicates on an interrupt that is a result of access the CPMEM or the DP memory in user mode 0 Interrupt is cleared. 1 Interrupt is requested.
27 Reserved	This read-only field is reserved and always has the value 0.
26 IC_BAYER_ FRM_LOST_ ERR	This bit indicates on an interrupt that is a result of IC's Bayer frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IC_ENC_FRM_ LOST_ERR	This bit indicates on an interrupt that is a result of IC's encoding frame lost.

Table continues on the next page...

IPUx_INT_STAT_10 field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
24 IC_VF_FRM_LOST_ERR	This bit indicates on an interrupt that is a result of IC's view finder frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
23 Reserved	This read-only field is reserved and always has the value 0.
22 DI1_TIME_OUT_ERR	DI1 time out error interrupt This bit indicates on the interrupt that is a result of a time out error during a read access via DI1
21 DI0_TIME_OUT_ERR	DI0 time out error interrupt This bit indicates on the interrupt that is a result of a time out error during a read access via DI0
20 DI1_SYNC_DISP_ERR	DI1 Synchronous display error interrupt This bit indicates on the interrupt that is a result of an error during access to a synchronous display via DI1
19 DI0_SYNC_DISP_ERR	DI0 Synchronous display error interrupt This bit indicates on the interrupt that is a result of an error during access to a synchronous display via DI0
18 DC_TEARING_ERR_6	Tearing Error #6 interrupt This bit indicates on the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 6
17 DC_TEARING_ERR_2	Tearing Error #2 interrupt This bit indicates on the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 2
16 DC_TEARING_ERR_1	Tearing Error #1 interrupt This bit indicates on the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 1
15–4 Reserved	This read-only field is reserved and always has the value 0.
3 SMFC3_FRM_LOST	Frame Lost of SMFC channel 3 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 3 0 Interrupt is cleared. 1 Interrupt is requested.
2 SMFC2_FRM_LOST	Frame Lost of SMFC channel 2 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 2 0 Interrupt is cleared. 1 Interrupt is requested.
1 SMFC1_FRM_LOST	Frame Lost of SMFC channel 1 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 1 0 Interrupt is cleared. 1 Interrupt is requested.

Table continues on the next page...

IPUx_INT_STAT_10 field descriptions (continued)

Field	Description
0 SMFC0_FRM_LOST	Frame Lost of SMFC channel 0 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 0 0 Interrupt is cleared. 1 Interrupt is requested.

37.5.62 Interrupt Status Register 11 (IPUx_INT_STAT_11)

IPU status registers are not stored in the SRM during power gating mode.This register contains part of IPU interrupts status bits. The status bits of the end-of-band indication (EOBND) of DMA Channels interrupts [31:0] can be found in this register.

- Hide VDOA_SYNC for all versions
- Show VDOA_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.

Address: Base address + 228h offset

IPUx_CUR_BUF_1 field descriptions (continued)

Field	Description
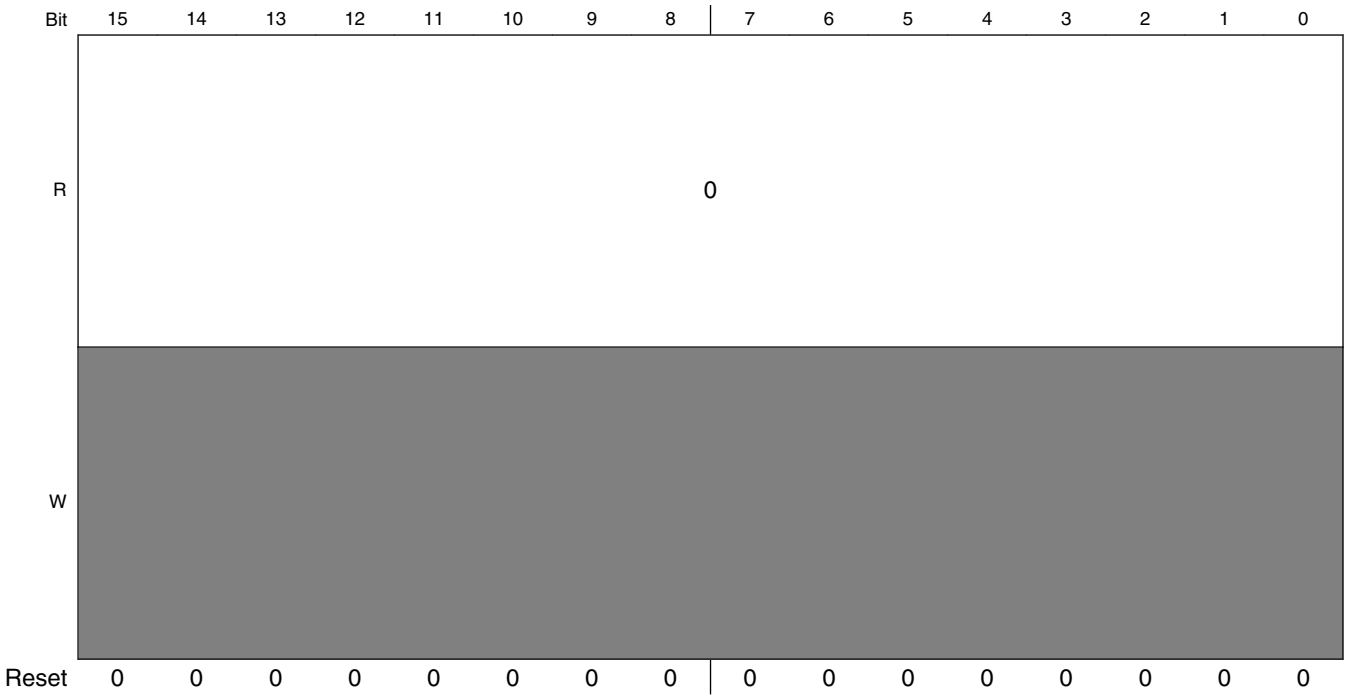
8 DMA_CH_CUR_BUF_40	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
7–2 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
1 DMA_CH_CUR_BUF_33	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
0 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

37.5.69 Alternate Current Buffer Register 0 (IPUx_ALT_CUR_0)

This register contains the current buffer status information bit for each DMA channel.

Address: Base address + 244h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0		DMA_CH_ALT_CUR_BUF_29	0				DMA_CH_ALT_CUR_BUF_24	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



IPUx_ALT_CUR_0 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
29 DMA_CH_ALT_ CUR_BUF_29	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
28–25 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
24 DMA_CH_ALT_ CUR_BUF_24	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

37.5.70 Alternate Current Buffer Register 1 (IPUx_ALT_CUR_1)

This register contains the current buffer status information bit for each DMA channel. The register is shown in VDI Plane Size Register 4 , and the register fields are described in VDI Plane Size Register 4 .

Address: Base address + 248h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IPUx_ALT_CUR_1 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
20 DMA_CH_ALT_CUR_BUF_52	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
19–10 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
9 DMA_CH_ALT_CUR_BUF1_n	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

IPUx_ALT_CUR_1 field descriptions (continued)

Field	Description
	0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
8–2 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
1 DMA_CH_ALT_ CUR_BUF0_n	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
0 Reserved	This read-only field is reserved and always has the value 0. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

37.5.71 Shadow Registers Memory Status Register (IPUx_SRM_STAT)

The register contains status bits of SRM updates. There is a bit for each block. The bit is set when the SRM is currently updating the module's registers. When the SRM completes updating the registers of the block the bit is cleared. SW should not update the block's registers while it is being updated by the SRM.

Address: Base address + 24Ch offset

IPUx_DISP_TASKS_STAT field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value 0.
11 DC_ASYNC2_CUR_FLOW	Current asynchronous #2 flow via the DC 1 alternate flow 0 main flow
10–8 DC_ASYNCH2_STAT	Status of the Asynchronous flow #2 through the DC 000 IDLE - the task is idle 001 PRIM_ACTIVE - The primary flow of this task is currently active 010 ALT_ACTIVE - The alternate flow of this task is currently active 011 UPDATE_PARAM - The FSU is busy updating parameters from the SRM 100 PAUSE - The task is paused 101 Reserved 110 Reserved 111 Reserved
7–6 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

IPUx_DISP_TASKS_STAT field descriptions (continued)

Field	Description
5–4 DC_ASYNC1_ STAT	Status of the Asynchronous flow #1 through the DC (ch 28) 00 IDLE - The task is idle 01 ACTIVE - This task is currently active 10 WAIT_FOR_ READY - The task is waiting for a buffer to be ready
3 DP_ASYNC_ CUR_FLOW	Current asynchronous flow via the DP 1 alternate flow 0 main flow
DP_ASYNC_ STAT	Status of the Asynchronous flow through the DP 000 IDLE - the task is idle 001 PRIM_ACTIVE - The primary flow of this task is currently active 010 ALT_ACTIVE - The alternate flow of this task is currently active 011 UPDATE_PARAM - The FSU is busy updating parameters from the SRM 100 PAUSE - The task is paused 101 Reserved 110 Reserved 111 Reserved

37.5.74 Triple Current Buffer Register 0 (IPUx_TRIPLE_CUR_BUF_0)

This register contains the current buffer status information for triple buffer mode for each DMA channel.

- Hide VPU_SUB_FRAME_SYNC for all versions
- Show VPU_SUB_FRAME_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.
- This requires some sophisticated conditional tag settings

Address: Base address + 258h offset

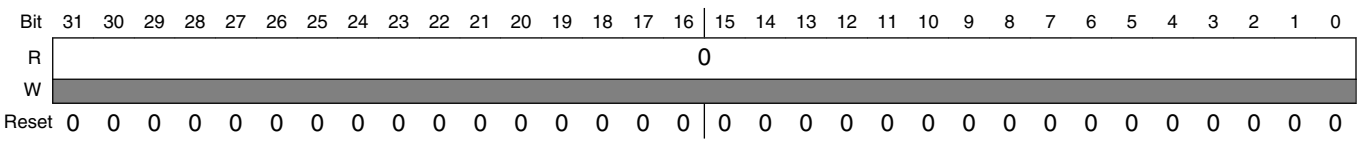
IPUx_TRIPLE_CUR_BUF_2 field descriptions

Field	Description
Reserved	This read-only field is reserved and always has the value 0. 00 Current buffer used by DMA is buffer 0. 01 Current buffer used by DMA is buffer 1. 10 Current buffer used by DMA is buffer 2.

37.5.76 Triple Current Buffer Register 3 (IPUx_TRIPLE_CUR_BUF_3)

This register contains the current buffer status information for triple buffer mode for each DMA channel.

Address: Base address + 264h offset



IPUx_TRIPLE_CUR_BUF_3 field descriptions

Field	Description
Reserved	This read-only field is reserved and always has the value 0. 00 Current buffer used by DMA is buffer 0. 01 Current buffer used by DMA is buffer 1. 10 Current buffer used by DMA is buffer 2.

37.5.76 IPU Channels Buffer 0 Ready 0 Register (IPUx_CH_BUF0_RDY0)

The register contains buffer 0 ready control information for 32 IPU's DMA channels (31-0). This register can be a write one to set or a write one to clear according to the **IPU_CH_BUF0_RDY0_CLR bit**.

The register is shown in IPU Channels Buffer 0 Ready 0 Register (IPU_CH_BUF0_RDY0), and the register fields are described in IPU Channels Buffer 0 Ready 0 Register (IPU_CH_BUF0_RDY0).

Address: Base address + 268h offset

IPUx_IDMAC_CONF field descriptions

Field	Description
31–26 -	This field is reserved. Reserved, should be cleared.
25 USED_BUFS_EN_R	Enables the limit on the number of pending non real time read requests.
24–21 USED_BUFS_MAX_R	Limit the number of pending non real time read requests. The value can be between 0 to 8. This field has no affect if USED_BUFS_EN_R is cleared
20 USED_BUFS_EN_W	Enables the limit on the number of pending non real time write requests.

Table continues on the next page...

IPUx_IDMAC_CONF field descriptions (continued)

Field	Description
19–17 USED_BUFS_MAX_W	Limit the number of pending non real time write requests. The value can be between 0 to 6. This field has no affect if USED_BUFS_EN_W is cleared
16 P_ENDIAN	Pixel Endianness. The pixel Endianness must not be changed while any of the IDMAC channels is enabled. 0 little endian 1 Big endian
15–6 -	This field is reserved. Reserved, should be cleared.
5 RDI	Read Data Interleaving. This bit must match the slave read data interleaving support. If the AXI slave connected to the IPU supports read data interleaving then this bit must be set. If the AXI slave does not support read data interleaving then the IDMAC can utilize this and issue more address phases on read. In that case it is recommended to have this bit cleared. 0 The AXI slave does not support read data interleaving 1 The AXI slave supports read data interleaving
4–3 WIDPT	Write Interleaving Depth These 2 bits define the Write Interleaving Depth of the AXI port. This bits should be configured by the user according to the AXI slave's Write Interleaving Depth. WIDPT defines the maximal number of active bursts (yet to be responded) with different IDs. IDMAC will block data phase if the next data's ID is new (no such ID active) and the number of active IDs is equal to WIDPT. 00 Write Interleaving Depth of 1 01 Write Interleaving Depth of 2 10 Write Interleaving Depth of 3 11 Write Interleaving Depth of 4
MAX_REQ_READ	Maximum Read Requests. This fields sets the maximum pending requests allowed in the AXI Read requests queue.

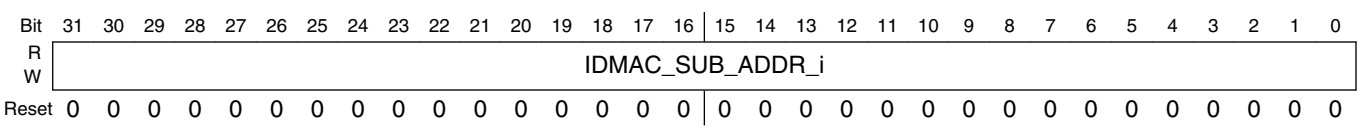
3–2 IDMAC_LOCK_46	IDMAC lock bits for channel [i] 00 The lock feature is disabled. The IDMAC will generate one AXI burst upon the assertion of the DMA request. 01 The IDMAC will generate two AXI bursts upon the assertion of the DMA request. 10 The IDMAC will generate four AXI bursts upon the assertion of the DMA request. 11 The IDMAC will generate eight AXI bursts upon the assertion of the DMA request.
IDMAC_LOCK_45	IDMAC lock bits for channel [i] 00 The lock feature is disabled. The IDMAC will generate one AXI burst upon the assertion of the DMA request. 01 The IDMAC will generate two AXI bursts upon the assertion of the DMA request. 10 The IDMAC will generate four AXI bursts upon the assertion of the DMA request. 11 The IDMAC will generate eight AXI bursts upon the assertion of the DMA request.

37.5.97 IDMAC Channel Alternate Address 0 Register (IPUx_IDMAC_SUB_ADDR_0)

Address: Base address + 802Ch offset

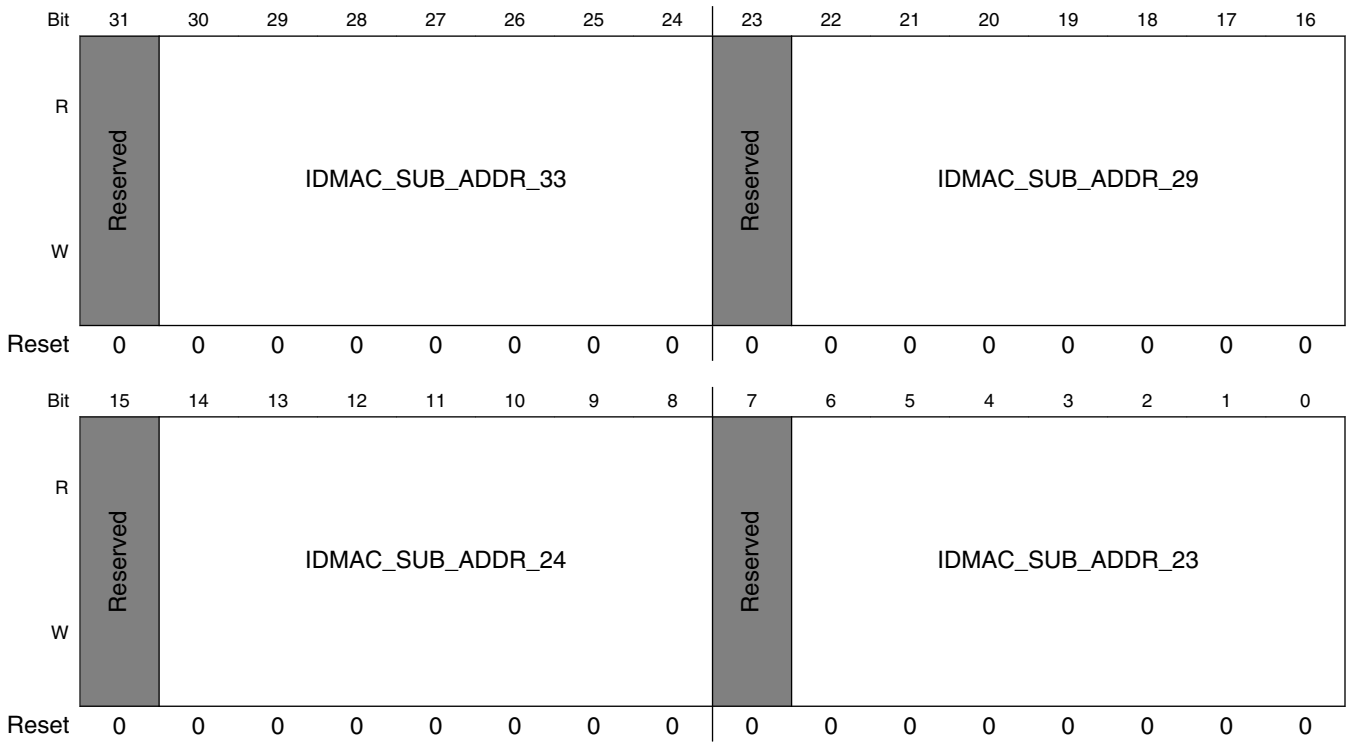


IPUx_IDMAC_SUB_ADDR_0 field descriptions

Field	Description
IDMAC_SUB_ADDR_i	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR_i. The user must set each IDMAC_SUB_ADDR_i field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

37.5.98 IDMAC Channel Alternate Address 1 Register (IPUx_IDMAC_SUB_ADDR_1)

Address: Base address + 8030h offset



IPUx_IDMAC_SUB_ADDR_1 field descriptions

Field	Description
31 -	This field is reserved. Reserved.
30–24 IDMAC_SUB_ADDR_33	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR_i. The user must set each IDMAC_SUB_ADDR_i field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
23 -	This field is reserved. Reserved.
22–16 IDMAC_SUB_ADDR_29	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR_i. The user must set each IDMAC_SUB_ADDR_i field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

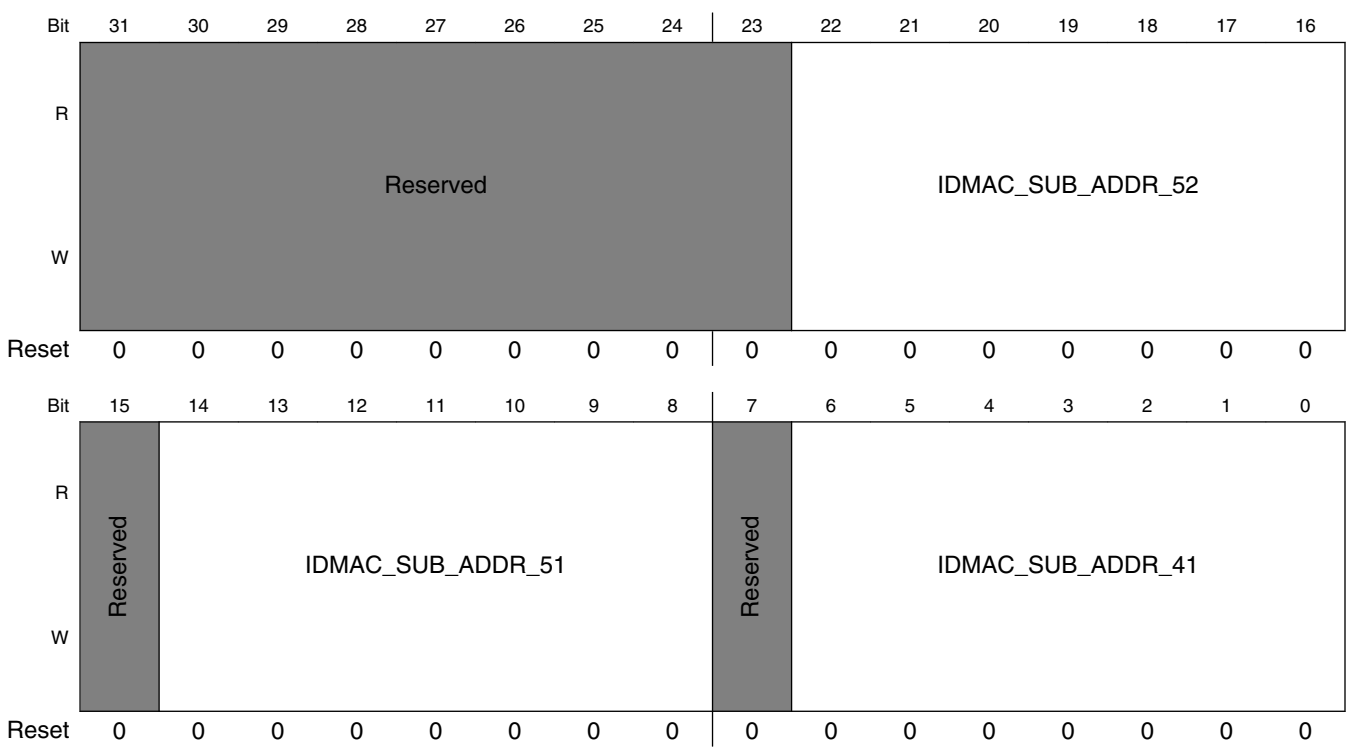
Table continues on the next page...

IPUx_IDMAC_SUB_ADDR_1 field descriptions (continued)

Field	Description
15 -	This field is reserved. Reserved.
14–8 IDMAC_SUB_ADDR_24	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR_i. The user must set each IDMAC_SUB_ADDR_i field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
7 -	This field is reserved. Reserved.
IDMAC_SUB_ADDR_23	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR_i. The user must set each IDMAC_SUB_ADDR_i field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

37.5.99 IDMAC Channel Alternate Address 2 Register (IPUx_IDMAC_SUB_ADDR_2)

Address: Base address + 8034h offset



IPUx_IDMAC_SUB_ADDR_2 field descriptions

Field	Description
31–23 -	This field is reserved. Reserved.

Table continues on the next page...

IPUx_DP_CUR_POS_ALT field descriptions

Field	Description
31–27 DP_CYP_SYNC_ALT	CYP_ALT - Cursor Y Position Represents the cursors vertical starting position Y in pixel count (from 0 to CYH).Live View Resolution Mode for the alternative flow.
26–16 DP_CYH_SYNC_ALT	CYH_ALT - Cursor Height Specifies the height of the hardware cursor in pixels.
15–11 DP_CXP_SYNC_ALT	CXP_ALT - Cursor X Position Represents the cursors horizontal starting position X in pixel count (from 0 to CXW) for the alternative flow.

Table continues on the next page...

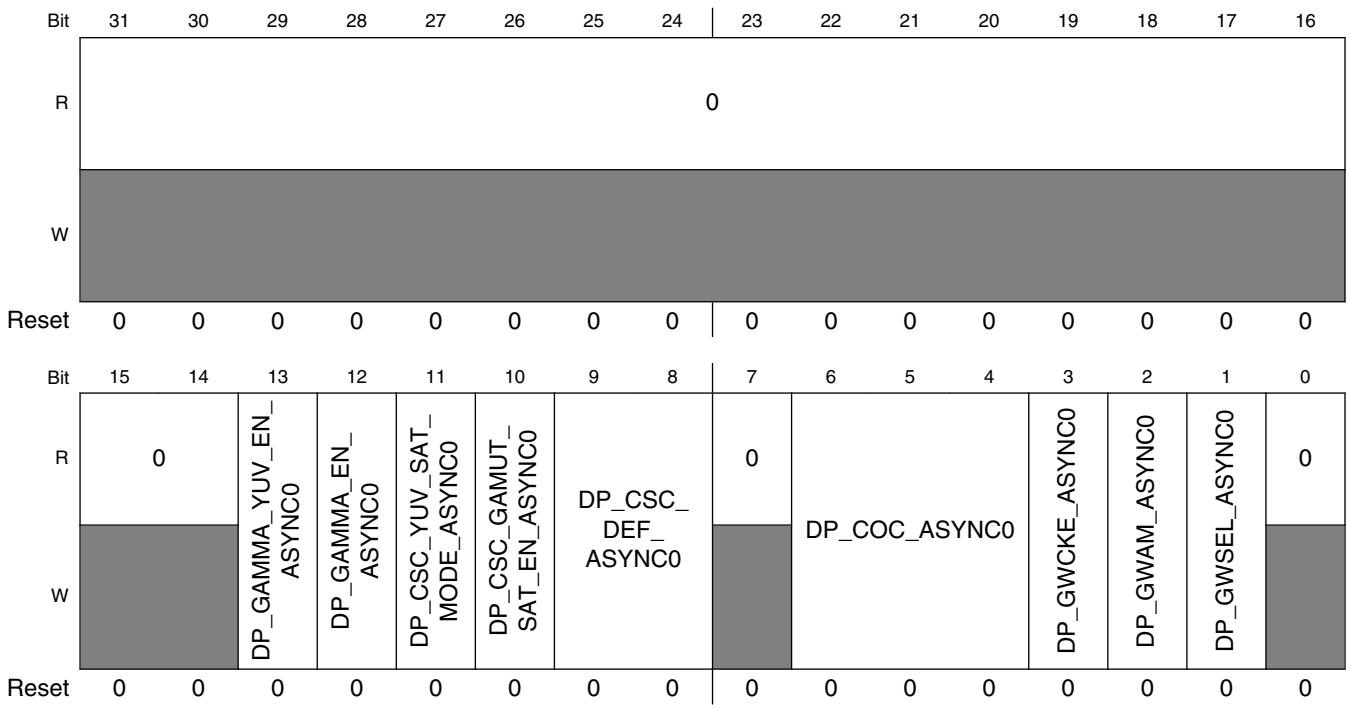
IPUx_DP_CUR_POS_ALT field descriptions (continued)

Field	Description
DP_CXW_ SYNC_ALT	CXW_ALT - Cursor Width. Specifies the width of the hardware cursor in pixels for the alternative flow.

37.5.119 DP Common Configuration Async 0 Flow Register (IPUx_DP_COM_CONF_ASYNC0)

This register contains common configuration parameters for the DP.

Address: Base address + 1_8060h offset



IPUx_DP_COM_CONF_ASYNC0 field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 DP_GAMMA_ YUV_EN_ ASYNC0	GAMMA's YUV mode enable for async flow 0 0 YUV mode is OFF. 1 YUV mode is ON.
12 DP_GAMMA_ EN_ASYNC0	GAMMA_EN - Gamma correction block enable bit

Table continues on the next page...

IPUx_DP_COM_CONF_ASYNC0 field descriptions (continued)

Field	Description
	0 disable 1 enable
11 DP_CSC_YUV_SAT_MODE_ASYNC0	CSC_YUV_SAT_MODE YUV saturation mode for color space conversion 0 Y/U/V range 0 -255 1 Y range 16-235, U/V range 16-240
10 DP_CSC_GAMUT_SAT_EN_ASYNC0	CSC_GAMUT_SAT_EN Indicate if GAMUT saturation is enabled 0 disable GAMUT mapping 1 enable GAMUT mapping
9–8 DP_CSC_DEF_ASYNC0	CSC_DEF Enable or disable Color Space Conversion. 00 CSC disable 01 CSC enable after combining 10 CSC enable before combining on BG channel 11 CSC enable before combining on FG channel
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 DP_COC_ASYNC0	COC - Cursor Operation Control Controls the format of the cursor and the type of arithmetic operations 000 Transparent, cursor is disabled. 001 Full cursor. 010 Reversed cursor. 011 AND between full plane and cursor. 100 Reserved 101 OR between full plane and cursor. 110 XOR between full plane and cursor. 111 Reserved
3 DP_GWCKE_ASYNC0	GWCKE - Graphic Window Color Keying Enable Enable or disable graphic window color keying. 1 Enable color keying of graphic window 0 Disable color keying of graphic window
2 DP_GWAM_ASYNC0	GWAM - Graphic Window Alpha Mode Select the use of Alpha to be global or local. 1 Global Alpha. 0 Local Alpha.
1 DP_GWSEL_ASYNC0	GWSEL - Graphic Window Select Select graphic window to be on partial plane or full plane.

Table continues on the next page...

IPUx_DP_COM_CONF_ASYNC0 field descriptions (continued)

Field	Description
	1 Graphic window is partial plane. 0 Graphic window is full plane.5
0 Reserved	This read-only field is reserved and always has the value 0.

37.5.120 DP Graphic Window Control Async 0 Flow Register (IPUx_DP_GRAPH_WIND_CTRL_ASYNC0)

This register contains common configuration parameters for the DP.

Address: Base address + 1_8064h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

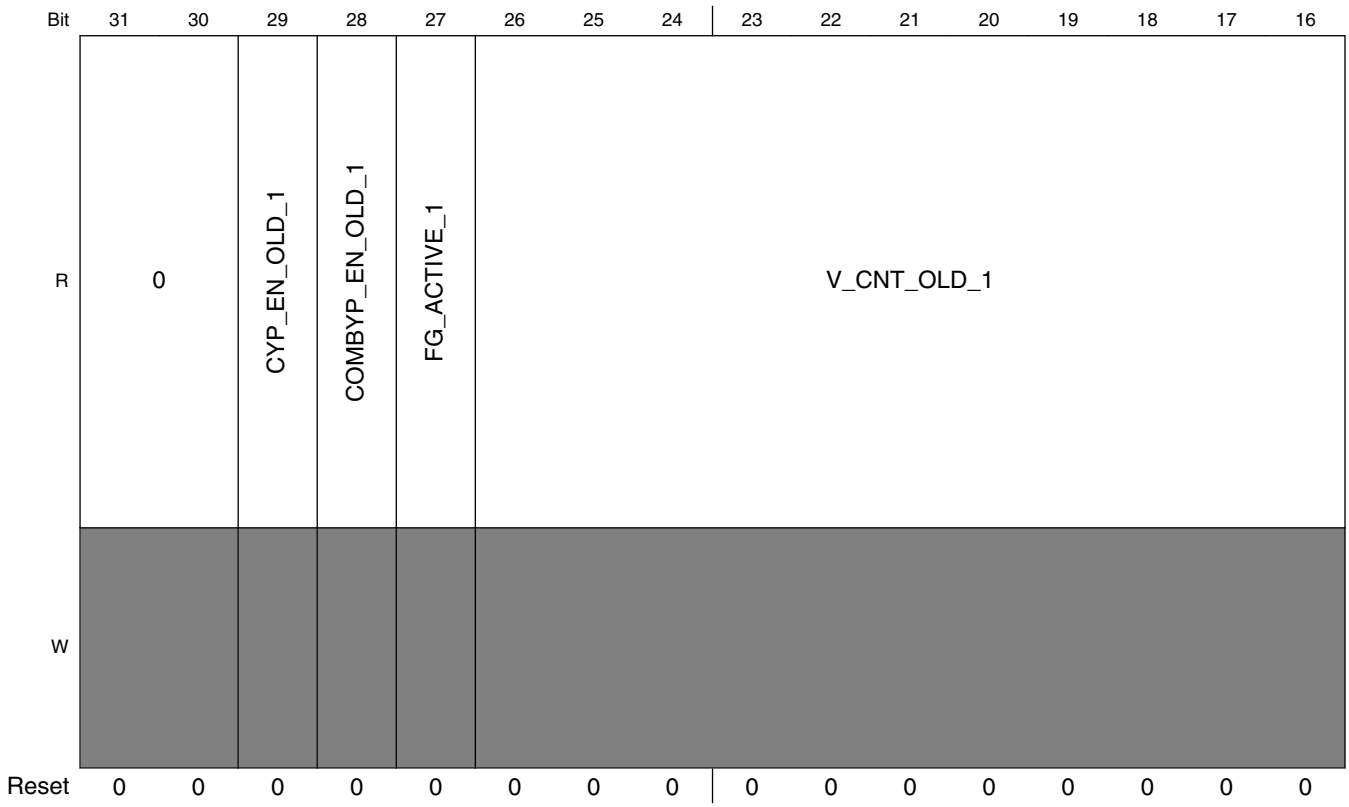
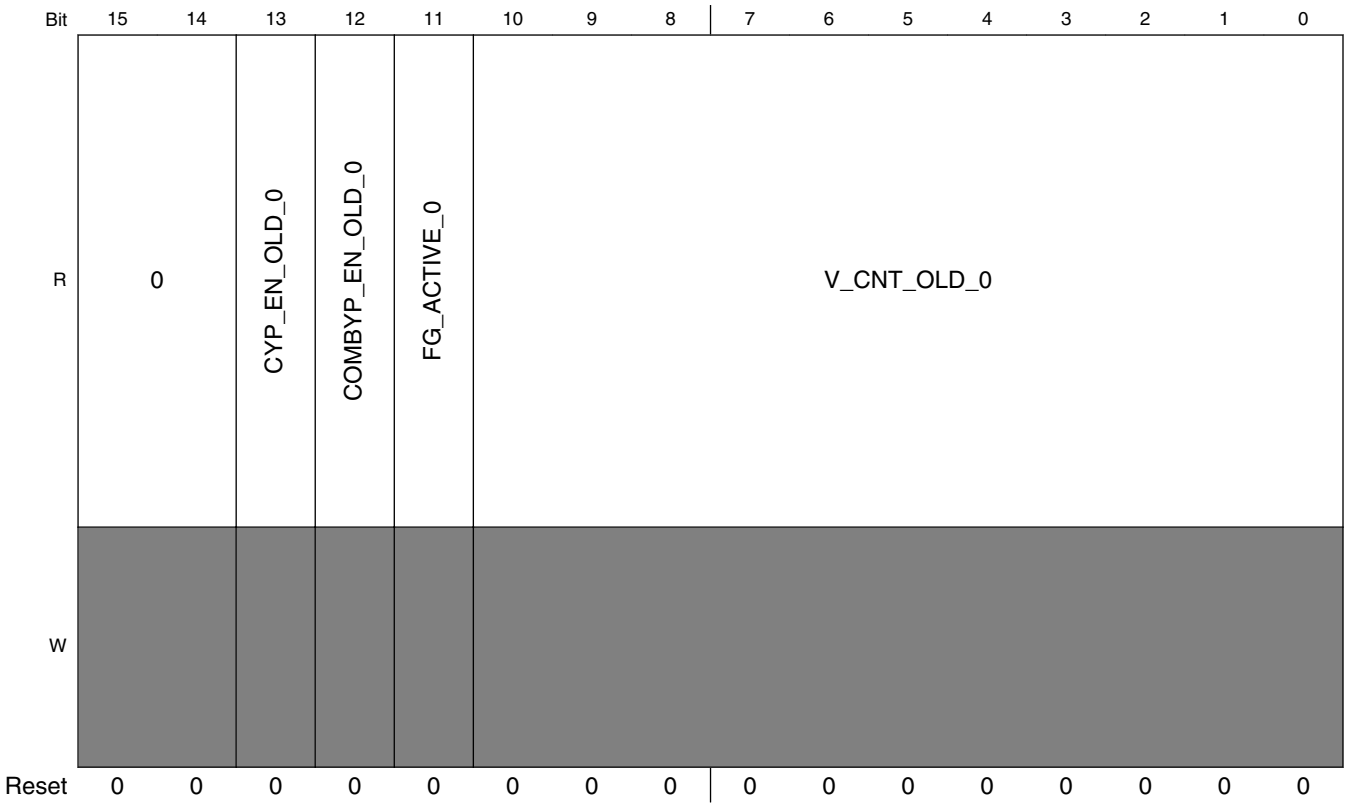
IPUx_DP_GRAPH_WIND_CTRL_ASYNC1 field descriptions

Field	Description
31–24 DP_GWAV_ASYNC1	GWAV - Graphic Window Alpha Value Defines the alpha value of graphic window used for alpha blending between graphic window and full plane. The Value the number that writing to GWAV register. The Actual Value the number, that insert to calculation in Combining Module. If Value = < 0.5- 1/256 (01111111) then Actual Value = Value. If Value >= 0.5 (10000000), then Actual Value = Value + 1/256. 00000000 Actual value is 00000000; Graphic window totally opaque i.e. overlay on LCD screen 01111111 Actual value is 01111111; 10000000 Actual value is 10000001 10000001 Actual value is 10000010 11111110 Actual value is 11111111 11111111 Actual value is 100000000;Graphic window totally transparent i.e. not displayed on LCD screen
23–16 DP_GWCKR_ASYNC1	GWCKR - Graphic Window Color Keying Red Component Defines the red component of graphic window color keying. 00000000 No red 11111111 Full red
15–8 DP_GWCKG_ASYNC1	GWCKG - Graphic Window Color Keying Green Component Defines the green component of graphic window color keying. 00000000 No Green 11111111 Full Green
DP_GWCKB_ASYNC1	GWCKB - Graphic Window Color Keying Blue Component Defines the blue component of graphic window color keying. 00000000 No blue 11111111 Full blue

37.5.132 DP Debug Status Register (IPUx_DP_DEBUG_STAT)

Address: Base address + 1_80C0h offset





IPUx_DP_DEBUG_STAT field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0.
29 CYP_EN_OLD_1	The async flow has been broken in the middle of a cursor (This filed is relevant for debug unit #1)
28 COMBYP_EN_OLD_1	the async1 flow has been broken in the middle of combining (This filed is relevant for debug unit #1)
27 FG_ACTIVE_1	Displaying the partial frame has been started (This filed is relevant for debug unit #1)
26–16 V_CNT_OLD_1	The exact row where the async flow has been broken (This filed is relevant for debug unit #0)
15–14 Reserved	This read-only field is reserved and always has the value 0.
13 CYP_EN_OLD_0	The async flow has been broken in the middle of a cursor (This filed is relevant for debug unit #0)
12 COMBYP_EN_OLD_0	the async flow has been broken in the middle of combining (This filed is relevant for debug unit #0)
11 FG_ACTIVE_0	Displaying the partial frame has been started for async flow (This filed is relevant for debug unit #0)
V_CNT_OLD_0	The exact row where the async flow has been broken (This filed is relevant for debug unit #0)

37.5.133 DP Partial Plane Window Position Async 1 Flow Register (IPUx_DP_FG_POS_ASYNC1)

The DP partial plane Window Position Register is used to determine the starting position of the partial plane window relative to BG window position.

This Register is used for the synchronous flow only.

Address: Base address + 1_80C4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_DP_CUR_POS_ASYNC1 field descriptions

Field	Description
31–27 DP_CYP_ ASYNC1	CYP - Cursor Y Position Represents the cursors vertical starting position Y in pixel count (from 0 to CYH).Live View Resolution Mode.
26–16 DP_CYH_ ASYNC1	CYH - Cursor Height Specifies the height of the hardware cursor in pixels.
15–11 DP_CXP_ ASYNC1	CXP - Cursor X Position Represents the cursors horizontal starting position X in pixel count (from 0 to CXW).
DP_CXW_ ASYNC1	CXW - Cursor Width. Specifies the width of the hardware cursor in pixels.

37.5.135 DP Color Cursor Mapping Async 1 Flow Register (IPUx_DP_CUR_MAP_ASYNC1)

The LCD Color Cursor Mapping Register defines the color of the cursor in passive or TFT color modes.

Address: Base address + 1_80CCh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

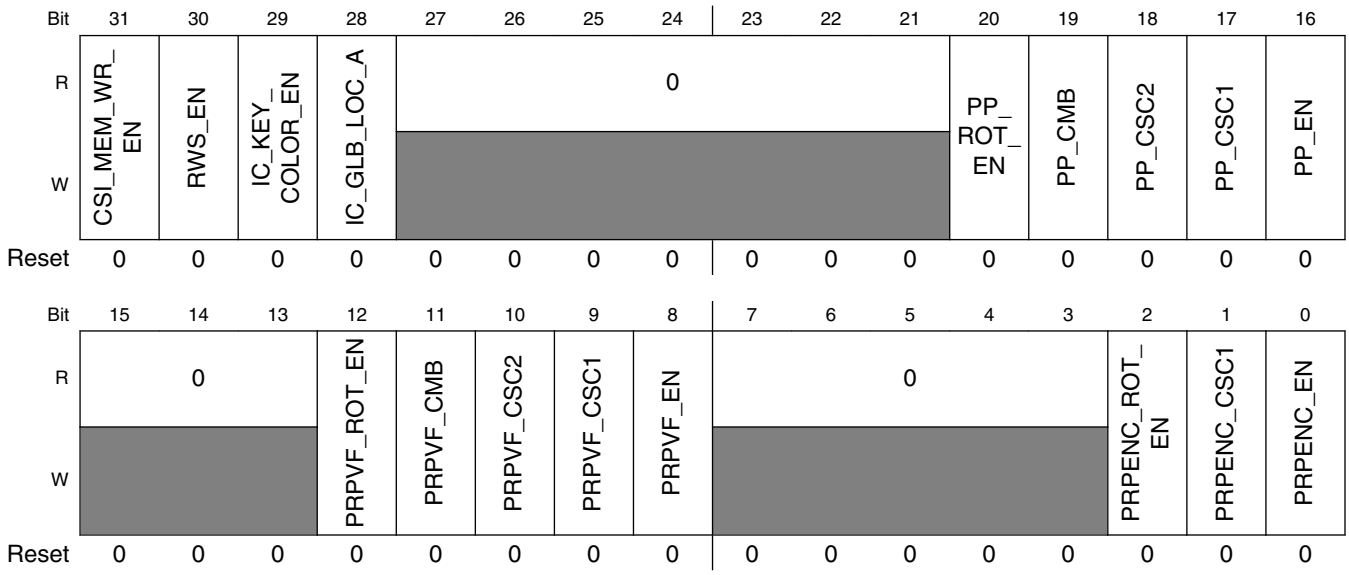
IPUx_DP_CSC_ASYNC1_1 field descriptions

Field	Description
31–30 DP_CSC_S2_ASYNC1	S0 parameter of color conversion. 00 scale factor of 2 01 scale factor of 1 10 scale factor of 0 11 scale factor of -1
29–16 DP_CSC_B2_ASYNC1	B0 parameter of color conversion.
15–14 DP_CSC_S1_ASYNC1	S0 parameter of color conversion. 00 scale factor of 2 01 scale factor of 1 10 scale factor of 0 11 scale factor of -1
DP_CSC_B1_ASYNC1	B0 parameter of color conversion.

37.5.141 IC Configuration Register (IPUx_IC_CONF)

This register contains control parameter for IC 3 tasks (pre-processing for encoding, pre-processing for view-finder and post processing).

Address: Base address + 2_0000h offset



IPUx_IC_CONF field descriptions

Field	Description
31 CSI_MEM_WR_EN	CSI direct memory write enable. This bit enables writing data from sensor directly to memory even when a raw sensor is not attached. 0 CSI direct writing to memory is disabled. 1 CSI direct writing to memory is enabled.
30 RWS_EN	Raw sensor enable. This bit indicate if a Raw sensor is attached (Bayer format). This bit is used together with the CSI_MEM_WR_EN bit as follows: CSI_MEM_WR_EN=0, RWS_EN=0 - data is fed from the CSI to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=0 - data is fed from the CSI to the IC for processing and also for writing to the system memory; CSI_MEM_WR_EN=0, RWS_EN=1 - data is fed from the CSI to the system memory (via the IC) and from the system memory to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=1 - non-valid configuration. 0 Raw sensor is not attached. 1 Raw sensor is attached.
29 IC_KEY_COLOR_EN	Key Color enable. This bit enables the key color feature.

Table continues on the next page...

IPUx_IC_CONF field descriptions (continued)

Field	Description
	0 Key color is disabled. 1 Key color is enabled.
28 IC_GLB_LOC_A	Global Alpha. This bit select the source of Alpha parameter. 0 Alpha parameter is local. 1 Alpha parameter is global.
27–21 Reserved	This read-only field is reserved and always has the value 0.
20 PP_ROT_EN	Post-Processing Rotation Task enable. This bit enable Post-Processing Rotation Task. 0 Rotation is disabled. 1 Rotation is enabled.
19 PP_CMB	Post-Processing Task combining enable. This bit enables combining. 0 Combining is disabled. 1 Combining is enabled.
18 PP_CSC2	Post-Processing Task color conversion RGB-->YUV enable. This bit enables YUV-->RGB. Reserved 0 RGB-->YUV is disabled. 1 RGB-->YUV is enabled.
17 PP_CSC1	Post-Processing Task color conversion YUV-->RGB enable. This bit enables YUV-->RGB. 0 YUV-->RGB is disabled. 1 YUV-->RGB is enabled.
16 PP_EN	Post-Processing Task enable. This bit enables the Post-Processing task. 0 Task is disabled. 1 Task is enabled.
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 PRPVF_ROT_EN	Preprocessing Rotation Task for viewfinder enable. This bit enable Preprocessing Rotation Task for viewfinder. 0 Rotation is disabled. 1 Rotation is enabled.
11 PRPVF_CMB	Preprocessing Task for View-Finder combining enable. This bit enables combining. 0 Combining is disabled. 1 Combining is enabled.
10 PRPVF_CSC2	Reserved
9 PRPVF_CSC1	Pre-processing task for view-finder first color conversion enable. This bit enables first color conversion. 0 First color conversion is disabled. 1 First color conversion is enabled.
8 PRPVF_EN	Preprocessing Task for View-Finder enable. This bit enables the View-Finder task.

Table continues on the next page...

IPUx_IC_CONF field descriptions (continued)

Field	Description
	0 Task is disabled. 1 Task is enabled.
7–3 Reserved	This read-only field is reserved and always has the value 0.
2 PRPENC_ROT_EN	Preprocessing Rotation Task for encoding enable. This bit enable Preprocessing Rotation Task for encoding. 0 Rotation is disabled. 1 Rotation is enabled.
1 PRPENC_CSC1	Preprocessing Task for encoding color conversion enable. This bit enables color conversion. 0 Color conversion is disabled. 1 Color conversion is enabled.
0 PRPENC_EN	Preprocessing Task for encoding enable. This bit enables the encoding task. 0 Task is disabled. 1 Task is enabled.

37.5.142 IC Preprocessing Encoder Resizing Coefficients Register (IPUx_IC_PRP_ENC_RSC)

This register contains the resizing and downsizing parameters for Preprocessing task for encoding.

Address: Base address + 2_0004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_IC_PRP_ENC_RSC field descriptions

Field	Description
31–30 PRPENC_DS_R_V	Preprocessing task for encoding Downsizing vertical Ratio. This field contains the downsizing vertical coefficient of Preprocessing for Encoding.
29–16 PRPENC_RS_R_V	Preprocessing task for encoding Resizing vertical Ratio. This field contains the resizing vertical coefficient of Preprocessing for Encoding. Resizing Ratio is equal to PRPENC_RS_R_V: M

Table continues on the next page...

IPUx_IC_PRP_ENC_RSC field descriptions (continued)

Field	Description
	Where M = 2^13; SI - input size; SO - output size PRPENC_RS_R_V = floor(M*(SI-1)/(SO-1));
15–14 PRPENC_DS_R_H	Preprocessing task for encoding Downsizing horizontal Ratio. This field contains the downsizing horizontal coefficient of Preprocessing for Encoding. Values: 00 1 01 2 10 4 11 RSV
PRPENC_RS_R_H	Preprocessing task for encoding Resizing horizontal Ratio. This field contains the resizing horizontal coefficient of Preprocessing for Encoding. Resizing Ratio is equal to PRPENC_RS_R_H: M Where M = 2^13; SI - input size; SO - output size PRPENC_RS_R_H = floor(M*(SI-1)/(SO-1));

37.5.143 IC Preprocessing View-Finder Resizing Coefficients Register (IPUx_IC_PRP_VF_RSC)

This register contains the resizing and downsizing parameters for preprocessing task for display.

Address: Base address + 2_0008h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

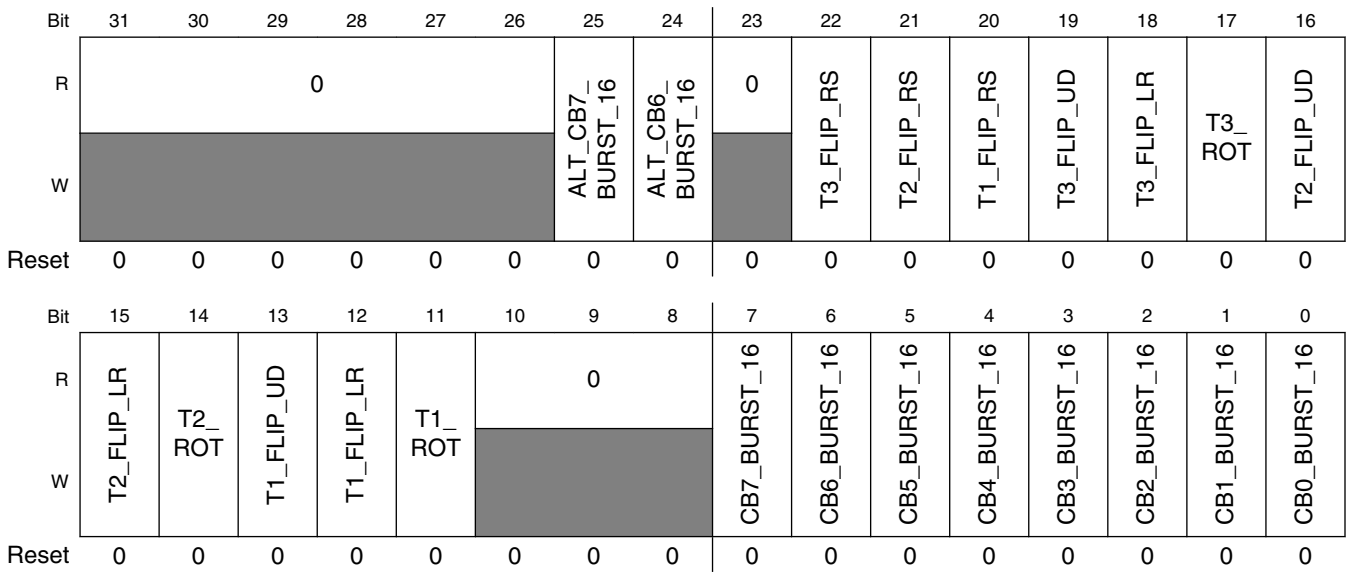
IPUx_IC_CMBP_2 field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23–16 IC_KEY_ COLOR_R	Key Color Red.
15–8 IC_KEY_ COLOR_G	Key Color Green.
IC_KEY_ COLOR_B	Key Color Blue.

37.5.147 IC IDMAC Parameters 1 Register (IPUx_IC_IDMAC_1)

Address: Base address + 2_0018h offset



IPUx_IC_IDMAC_1 field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value 0.
25 ALT_CB7_ BURST_16	Reserved
24 ALT_CB6_ BURST_16	Reserved
23 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

IPUx_IC_IDMAC_1 field descriptions (continued)

Field	Description
22 T3_FLIP_RS	LEFT/RIGHT flip for Post Processing (PP) task; his bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
21 T2_FLIP_RS	LEFT/RIGHT flip for View Finder (VF) task; this bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
20 T1_FLIP_RS	LEFT/RIGHT flip for Encoding (ENC) task; this bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
19 T3_FLIP_UD	UP/DOWN flip for Post Processing (PP) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 Vertical flip enable 0 no flip
18 T3_FLIP_LR	LEFT/RIGHT flip for Post Processing (PP) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
17 T3_ROT	Rotation for Post Processing (PP) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 90 degree rotation clockwise 0 no rotation
16 T2_FLIP_UD	UP/DOWN flip for View Finder (VF) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 Vertical flip enable 0 no flip
15 T2_FLIP_LR	LEFT/RIGHT flip for View Finder (VF) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip

Table continues on the next page...

IPUx_IC_IDMAC_1 field descriptions (continued)

Field	Description
14 T2_ROT	Rotation for View Finder (VF) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 90 degree rotation clockwise 0 no rotation
13 T1_FLIP_UD	UP/DOWN flip for Encoding (ENC) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 Vertical flip enable 0 no flip
12 T1_FLIP_LR	LEFT/RIGHT flip for Encoding (ENC) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
11 T1_ROT	Rotation for Encoding (ENC) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 90 degree rotation clockwise 0 no rotation
10–8 Reserved	This read-only field is reserved and always has the value 0.
7 CB7_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB7 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
6 CB6_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB6 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
5 CB5_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB5 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
4 CB4_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB4 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM

Table continues on the next page...

IPUx_IC_IDMAC_1 field descriptions (continued)

Field	Description
	0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
3 CB3_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB3 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
2 CB2_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB2 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
1 CB1_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB1 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
0 CB0_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB0 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111

37.5.148 IC IDMAC Parameters 2 Register (IPUx_IC_IDMAC_2)

Address: Base address + 2_001Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPUx_CSI0_SENS_CONF field descriptions

Field	Description
31 CSI0_DATA_EN_POL	Invert IPP_IND_SENSB_DATA_EN input. This bit selects the polarity of IPP_IND_SENSB_DATA_EN signal. 0 IPP_IND_SENSB_DATA_EN is directly applied to internal circuitry. 1 IPP_IND_SENSB_DATA_EN is inverted before applied to internal circuitry.
30 Reserved	This read-only field is reserved and always has the value 0.
29 CSI0_FORCE_EOF	Force End of frame This is a self clear bit allowing the user to force an End-of-frame event; This bit can be used in cases where the frame sent by the sensor was not completed. 1 force end of frame 0 no action
28 CSI0_JPEG_MODE	JPEG Mode - this bit defines the mode of the control signals when working in JPEG mode 1 The data is valid as long as HSYNC and VSYNC signals are active; HSYNC is valid for single frame 0 The frame starts withe the assertion of VSYNC. The frame ends on the next VSYNC or by setting the **CSI0_FORCE_EOF bit.**
27 CSI0_JPEG8_EN	JPEG8 enable bit 1 JPEG8 detection is enabled 0 JPEG8 is disabled
26–24 CSI0_DATA_DEST	These bits enable the destination of the data coming from the CSI. CSI0_DATA_DEST[0] - Reserved CSI0_DATA_DEST[1] - destination is IC CSI0_DATA_DEST[2] - destination is IDMAC via SMFC
23–16 CSI0_DIV_RATIO	DIV Ratio Clock division ratio minus 1. This field defines the division ratio of HSP_CLK into SENSB_MCLK: SENSB_MCLK rate = HSP_CLK rate /(DIV_RATIO+1)
15 CSI0_EXT_VSYNC	External VSYNC enable. This bits select between external and internal VSYNC. 0 Internal VSYNC mode. 1 External VSYNC mode.
14–11 CSI0_DATA_WIDTH	Data width. This field defines the number of bits per color. Values: 0000 4 bits per color 0001 8 bits per color 0010 9 bits per color 0011 10 bits per color 0100 11 bits per color 0101 12 bits per color 0110 13 bits per color 0111 14 bits per color 1000 15 bits per color 1001 16 bits per color

Table continues on the next page...

IPUx_CSI0_SENS_CONF field descriptions (continued)

Field	Description
10–8 CSI0_SENS_ DATA_FORMAT	Data format from the sensor. This field defines the data format for the input of the CSI sensor. Values: 000 full RGB or YUV444 001 YUV422 (YUYV...) 010 YUV422 (UYVY...) 011 Bayer or Generic data 100 RGB565 101 RGB555 110 RGB444 111 JPEG
7 CSI0_PACK_ TIGHT	CSI0 Pack Tight When the data format is YUV or RGB and the component's width is 9-16 bits, it can be sent to the memory in 2 different ways. 1 Three 10 bits components are packed into a 32 bit word. Color extension/reduction is performed 0 Each component is written as a 16 bit word where the MSB is written to bit #15, color extension is done for the remaining least significant bits.
6–4 CSI0_SENS_ PRTCL	Sensor Protocol. This bit defines the Sensor timing/data mode protocol. Values: 000 Gated clock mode 001 Non-gated clock mode 010 CCIR progressive mode (BT.656) 011 CCIR interlaced mode (BT.656) 100 CCIR progressive (BT.1120 DDR mode: data arrives on every edge of the clock) 101 CCIR progressive (BT.1120 SDR mode: data arrives only on the positive edge of the clock) 110 CCIR interlaced mode (BT.1120 DDR mode: data arrives on every edge of the clock) 111 CCIR interlaced mode (BT.1120 SDR mode: data arrives only on the positive edge of the clock)
3 CSI0_SENS_ PIX_CLK_POL	Invert Pixel clock input. This bit selects the polarity of pixel clock. 0 pixel clock is directly applied to internal circuitry. 1 pixel clock is inverted before applied to internal circuitry.
2 CSI0_DATA_ POL	Invert data input. This bit selects the polarity of data input. 0 data lines are directly applied to internal circuitry. 1 data lines are inverted before applied to internal circuitry.
1 CSI0_HSYNC_ POL	Invert IPP_IND_SENSB_HSYNC input. This bit selects the polarity of IPP_IND_SENSB_HSYNC signal. 0 IPP_IND_SENSB_HSYNC is directly applied to internal circuitry. 1 IPP_IND_SENSB_HSYNC is inverted before applied to internal circuitry.
0 CSI0_VSYNC_ POL	Invert IPP_IND_SENSB_VSYNC input. This bit selects the polarity of IPP_IND_SENSB_VSYNC signal. 0 IPP_IND_SENSB_VSYNC is not inverted before applied to internal circuitry. 1 IPP_IND_SENSB_VSYNC is inverted before applied to internal circuitry.

37.5.152 CSI0 Sense Frame Size Register (IPUx_CSI0_SENS_FRM_SIZE)

Address: Base address + 3_0004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

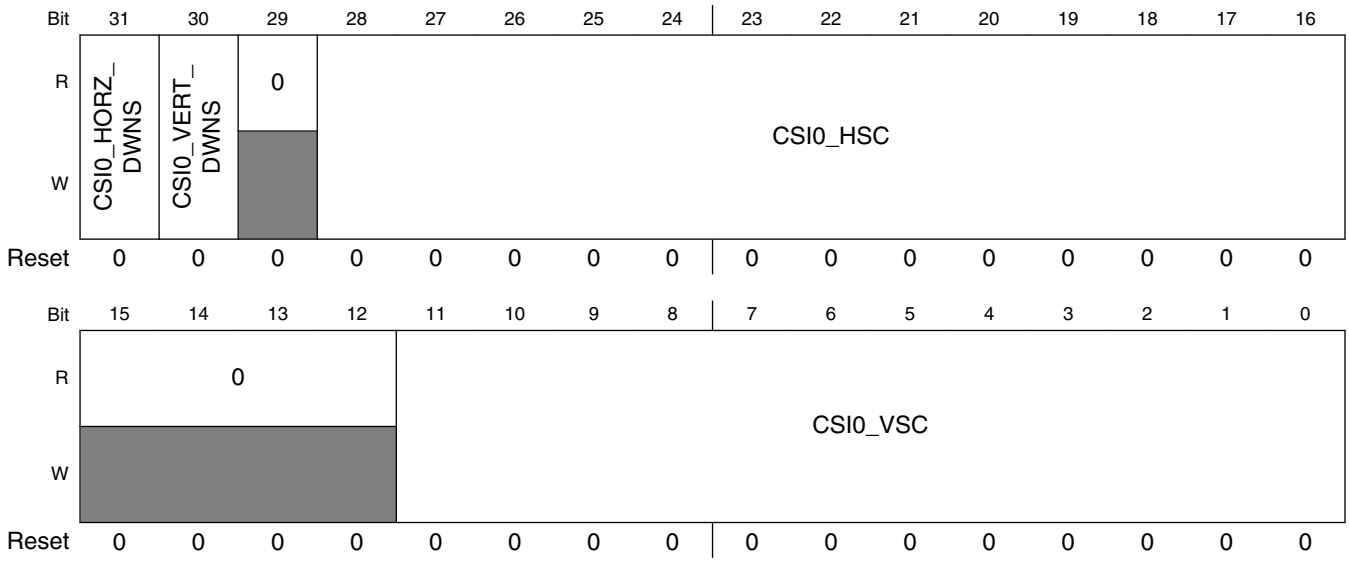
IPUx_CSI0_ACT_FRM_SIZE field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–16 CSI0_ACT_ FRM_HEIGHT	Actual frame height minus 1. This field defines the CSI output frame rows number minus 1.
15–13 Reserved	This read-only field is reserved and always has the value 0.
CSI0_ACT_ FRM_WIDTH	Actual frame width minus 1. This field defines the CSI output frame columns number minus 1.

37.5.154 CSI0 Output Control Register (IPUx_CSI0_OUT_FRM_CTRL)

Address: Base address + 3_000Ch offset

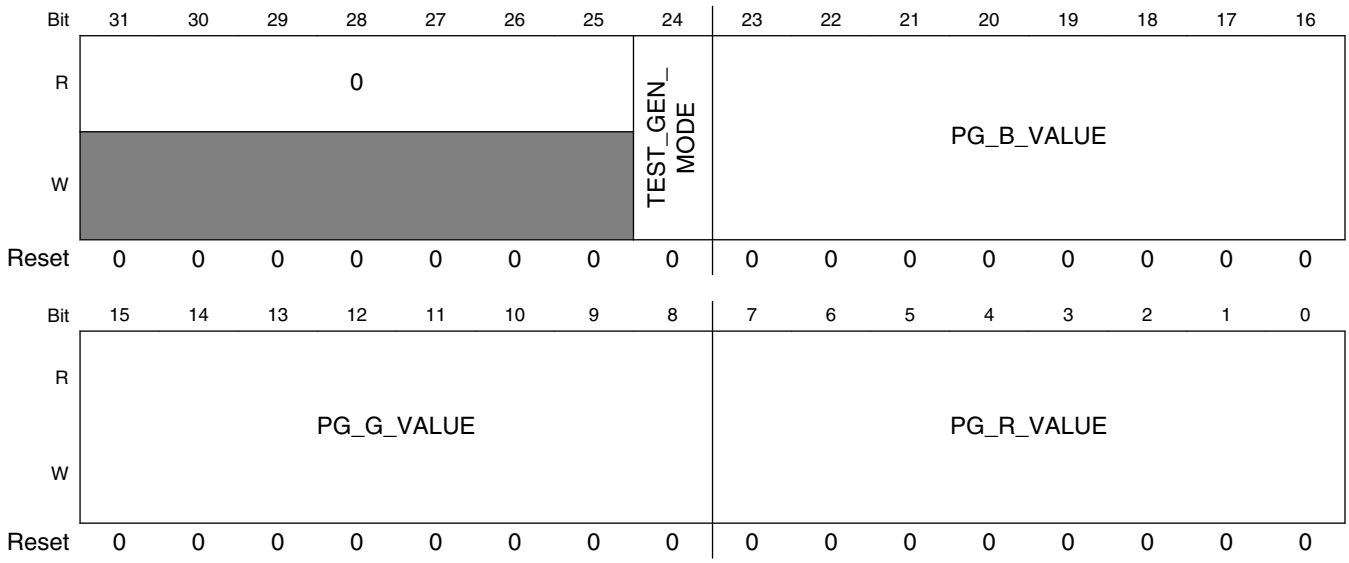


IPUx_CSI0_OUT_FRM_CTRL field descriptions

Field	Description
31 CSI0_HORZ_DWNS	Enable horizontal downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
30 CSI0_VERT_DWNS	Enable vertical downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
29 Reserved	This read-only field is reserved and always has the value 0.
28–16 CSI0_HSC	Horizontal skip. This field defines the number of columns to skip. In Interlaced mode this number refers to the number of lines per field.
15–12 Reserved	This read-only field is reserved and always has the value 0.
CSI0_VSC	Vertical skip. This field defines the number of rows to skip.

37.5.155 CSIO Test Control Register (IPUx_CSI0_TST_CTRL)

Address: Base address + 3_0010h offset

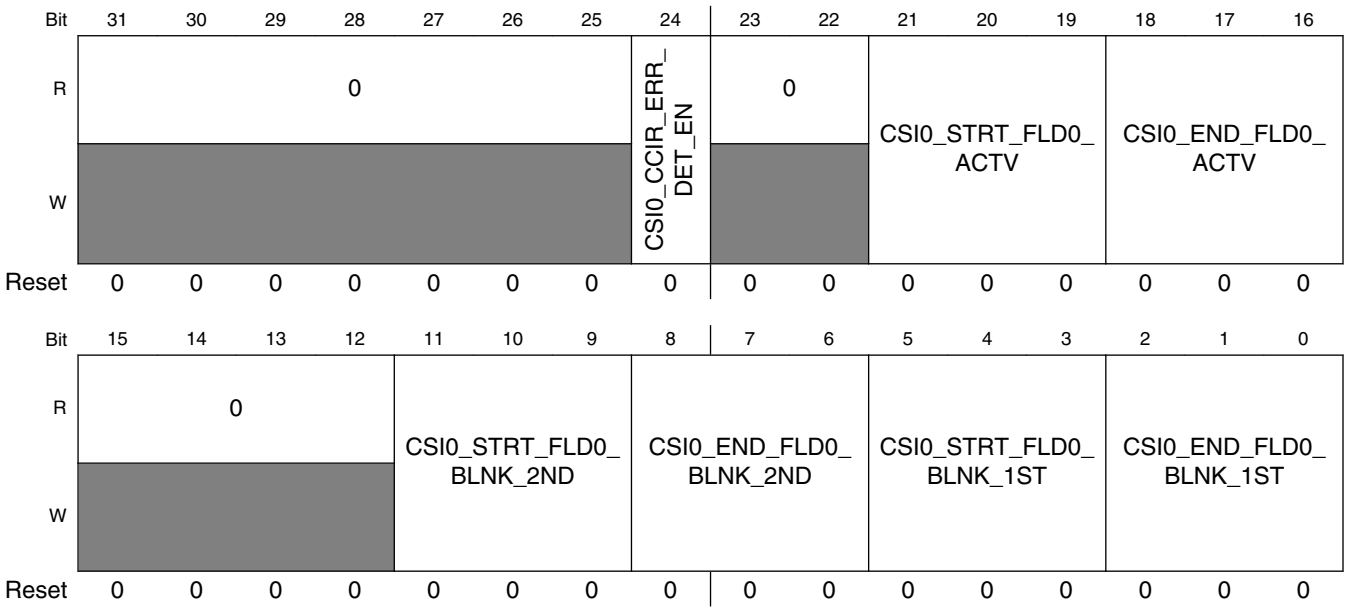


IPUx_CSI0_TST_CTRL field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 TEST_GEN_ MODE	Test generator mode. This bit activates the signal generation. 0 Test signal generator is inactive. 1 Test signal generator is active.
23–16 PG_B_VALUE	Pattern generator B value. This field selects the B value for the generated pattern of even pixel.
15–8 PG_G_VALUE	Pattern generator G value. This field selects the G value for the generated pattern of even pixel.
PG_R_VALUE	Pattern generator R value. This field selects the R value for the generated pattern of even pixel.

37.5.156 CSI0 CCIR Code Register 1 (IPUx_CSI0_CCIR_CODE_1)

Address: Base address + 3_0014h offset



IPUx_CSI0_CCIR_CODE_1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 CSI0_CCIR_ERR_DET_EN	Enable error detection and correction for CCIR interlaced mode with protection bit. 0 Error detection and correction is disabled. 1 Error detection and correction is enabled.
23–22 Reserved	This read-only field is reserved and always has the value 0.
21–19 CSI0_STRT_FLD0_ACTV	Start of field 0 active line command (interlaces mode). (In progressive mode, start of active line command mode).
18–16 CSI0_END_FLD0_ACTV	End of field 0 active line command (interlaces mode). (In progressive mode, end of active line command mode).
15–12 Reserved	This read-only field is reserved and always has the value 0.
11–9 CSI0_STRT_FLD0_BLNK_2ND	Start of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).
8–6 CSI0_END_FLD0_BLNK_2ND	End of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).

Table continues on the next page...

IPUx_CSI0_CCIR_CODE_1 field descriptions (continued)

Field	Description
5–3 CSI0_STRT_ FLD0_BLNK_ 1ST	Start of field 0 first blanking line command (interlaces mode). (In progressive mode this field indicates start of blanking line command).
CSI0_END_ FLD0_BLNK_ 1ST	End of field 0 first blanking line command (interlaces mode). (In progressive mode this field is ignored).

37.5.157 CSIO CCIR Code Register 2 (IPUx_CSI0_CCIR_CODE_2)

Address: Base address + 3_0018h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_CSI0_DI field descriptions

Field	Description
31–24 CSI0_MIPI_DI3	CSI0_MIPI_DI3 This field holds the Data Identifier #3 handled by the CSI.
23–16 CSI0_MIPI_DI2	CSI0_MIPI_DI2 This field holds the Data Identifier #2 handled by the CSI.
15–8 CSI0_MIPI_DI1	CSI0_MIPI_DI1 This field holds the Data Identifier #1 handled by the CSI
CSI0_MIPI_DI0	CSI0_MIPI_DI0 This field holds the Data Identifier #0 handled by the CSI; This is the main stream.

37.5.160 CSI0 SKIP Register (IPUx_CSI0_SKIP)

This register controls the frame skipping supported between CSI0 and the SMFC.

Address: Base address + 3_0024h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						CSI0_ID_2_SKIP		CSI0_SKIP_SMFC					CSI0_MAX_RATIO_SKIP_SMFC		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPUx_CSI0_SKIP field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 CSI0_ID_2_SKIP	CSI0 to SMFC Skipping ID. Data from the CSI0 to the SMFC has an ID associated with it. The ID is received from the MIPI interface. The skipping mechanism between the CSI0 and the SMFC can be used for only one ID. There is no skipping for data coming with ID different from the ID programed in this bits 00 - Skipping mechanism is activated on frames with ID equal to 00 01 - Skipping mechanism is activated on frames with ID equal to 01 10 - Skipping mechanism is activated on frames with ID equal to 10 11 - Skipping mechanism is activated on frames with ID equal to 11
7–3 CSI0_SKIP_SMFC	CSI0 SKIP SMFC These 5 bits define the skipping pattern of the frames send to the SMFC. Skipping is done for a set of frames. The number of frames in a set is defined at CSI0_MAX_RATIO_SKIP_SMFC. when CSI0_MAX_RATIO_SKIP_SMFC = 1 => CSI0_SKIP_SMFC[0] is used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 2 => CSI0_SKIP_SMFC[1:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 3 => CSI0_SKIP_SMFC[2:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 4 => CSI0_SKIP_SMFC[3:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 5 => CSI0_SKIP_SMFC[4:0] are used; Setting bit #n of CSI0_SKIP_SMFC means that the #n frame in the set is skipped. For example: if CSI0_MAX_RATIO_SKIP_SMFC = 4 and CSI0_SKIP_SMFC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI0_MAX_RATIO_SKIP_SMFC is set to 4

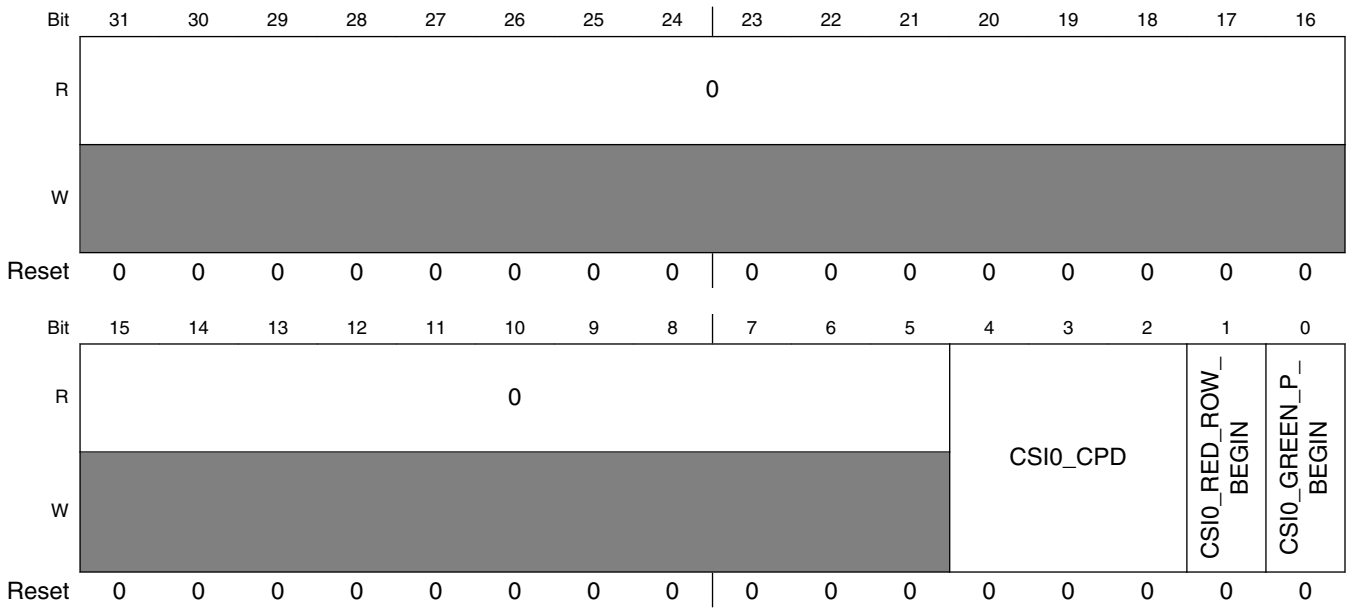
Table continues on the next page...

IPUx_CSI0_SKIP field descriptions (continued)

Field	Description
CSI0_MAX_RATIO_SKIP_SMFC	CSI0 Maximum Ratio Skip for SMFC These bits define the number of frames in a skipping set. The skipping number is equal to CSI0_MAX_RATIO_SKIP_SMFC+1; The maximum value of this bits is 5. When set to 0 the skipping is disabled.

37.5.161 CSI0 Compander Control Register (IPUx_CSIO_CPD_CTRL)

Address: Base address + 3_0028h offset



IPUx_CSIO_CPD_CTRL field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4–2 CSI0_CPD	CSI0_CPD These bits enable the compander in the path to different destination. CSI0_CPD[0] - CSI0_CPD[1] - Enable for the compander for data sent to the IC CSI0_CPD[2] - Enable for the compander for data sent to the IDMAC via SMFC If all the 3 bits are zero the compander is disabled Reserved
1 CSI0_RED_ROW_BEGIN	Color of first row in the frame. Reserved

Table continues on the next page...

IPUx_CSIO_CPD_CTRL field descriptions (continued)

Field	Description
	0 First row in the frame is GBGB. 1 First row in the frame is GRGR.
0 CSI0_GREEN_P_BEGIN	Color of first component in the frame. Reserved 0 First component in the frame is blue or red, depending from RED_ROW bit. 1 First component in the frame is green

37.5.162 CSI0 Red Component Compander Constants Register <i> (IPUx_CSIO_CPD_RC_i)

These registers contain CONSTANT <i> parameters used for companding of red component.

Address: Base address + 3_002Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPUx_CSI1_SENS_CONF field descriptions

Field	Description
31 CSI0_DATA_EN_POL	Invert IPP_IND_SENSB_DATA_EN input. This bit selects the polarity of IPP_IND_SENSB_DATA_EN signal. 0 IPP_IND_SENSB_DATA_EN is directly applied to internal circuitry. 1 IPP_IND_SENSB_DATA_EN is inverted before applied to internal circuitry.
30 Reserved	This read-only field is reserved and always has the value 0.
29 CSI1_FORCE_EOF	Force End of frame This is a self clear bit allowing the user to force an End-of-frame event; This bit can be used in cases where the frame sent by the sensor was not completed. 1 force end of frame 0 no action
28 CSI1_JPEG_MODE	JPEG Mode - this bit defines the mode of the control signals when working in JPEG mode 1 The data is valid as long as HSYNC and VSYNC signals are active; HSYNC is valid for single frame 0 The frame starts withe the assertion of VSYNC. The frame ends on the next VSYNC or by setting the **CSI0_FORCE_EOF bit**
27 CSI1_JPEG8_EN	JPEG8 enable bit 1 JPEG8 detection is enabled 0 JPEG8 is disabled

Table continues on the next page...

IPUx_CSI1_SENS_CONF field descriptions (continued)

Field	Description
26–24 CSI1_DATA_DEST	These bits enable the destination of the data coming from the CSI. CSI1_DATA_DEST[0] - Reserved CSI1_DATA_DEST[1] - destination is IC CSI1_DATA_DEST[2] - destination is IDMAC via SMFC
23–16 CSI1_DIV_RATIO	DIV Ratio Clock division ratio minus 1. This field defines the division ratio of HSP_CLK into SENSB_MCLK: SENSB_MCLK rate = HSP_CLK rate /(DIV_RATIO+1)
15 CSI1_EXT_VSYNC	External VSYNC enable. This bits select between external and internal VSYNC. 0 Internal VSYNC mode. 1 External VSYNC mode.
14–11 CSI1_DATA_WIDTH	Data width. This fields defines the number of bits per color. Values: 0000 4 bits per color 0000 Reserved 0001 8 bits per color 0010 9 bits per color 0010 Reserved 0011 10 bits per color 0100 11 bits per color 0100 Reserved 0101 12 bits per color 0101 Reserved 0110 13 bits per color 0110 Reserved 0111 14 bits per color 0111 Reserved 1000 15 bits per color 1000 Reserved 1001 16 bits per color
10–8 CSI1_SENS_DATA_FORMAT	Data format from the sensor. This field defines the data format for the input of the CSI sensor. Values: 000 full RGB or YUV444 001 YUV422 (YUYV...) 010 YUV422 (UYVY...) 011 Bayer or Generic data 100 RGB565 101 RGB555 110 RGB444 111 JPEG
7 CSI1_PACK_TIGHT	**CSI1 Pack Tight** When the data format is YUV or RGB and the component's width is 9-16 bits, it can be sent to the memory in 2 different ways

Table continues on the next page...

IPUx_CSI1_SENS_CONF field descriptions (continued)

Field	Description
	1 Three 10 bits components are packed into a 32 bit word. Color extension/reduction is performed 0 Each component is written as a 16 bit word where the MSB is written to bit #15, color extension is done for the remaining least significant bits.
6–4 CSI1_SENS_PRTCL	Sensor Protocol. This bit defines the Sensor timing/data mode protocol. Values: 000 Gated clock mode 001 Non-gated clock mode 010 CCIR progressive mode (BT.656) 011 CCIR interlaced mode (BT.656) 100 CCIR progressive (BT.1120 DDR mode: data arrives on every edge of the clock) 101 CCIR progressive (BT.1120 SDR mode: data arrives only on the positive edge of the clock) 110 CCIR interlaced mode (BT.1120 DDR mode: data arrives on every edge of the clock) 111 CCIR interlaced mode (BT.1120 SDR mode: data arrives only on the positive edge of the clock)
3 CSI1_SENS_PIX_CLK_POL	Invert Pixel clock input. This bit selects the polarity of pixel clock. 0 pixel clock is directly applied to internal circuitry. 1 pixel clock is inverted before applied to internal circuitry.
2 CSI1_DATA_POL	Invert data input. This bit selects the polarity of data input. 0 data lines are directly applied to internal circuitry. 1 data lines are inverted before applied to internal circuitry.
1 CSI1_HSYNC_POL	Invert IPP_IND_SENSB_HSYNC input. This bit selects the polarity of IPP_IND_SENSB_HSYNC signal. 0 IPP_IND_SENSB_HSYNC is directly applied to internal circuitry. 1 IPP_IND_SENSB_HSYNC is inverted before applied to internal circuitry.
0 CSI1_VSYNC_POL	Invert IPP_IND_SENSB_VSYNC input. This bit selects the polarity of IPP_IND_SENSB_VSYNC signal. 0 IPP_IND_SENSB_VSYNC is not inverted before applied to internal circuitry. 1 IPP_IND_SENSB_VSYNC is inverted before applied to internal circuitry.

37.5.173 CSI1 Sense Frame Size Register (IPUx_CSI1_SENS_FRM_SIZE)

Address: Base address + 3_8004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

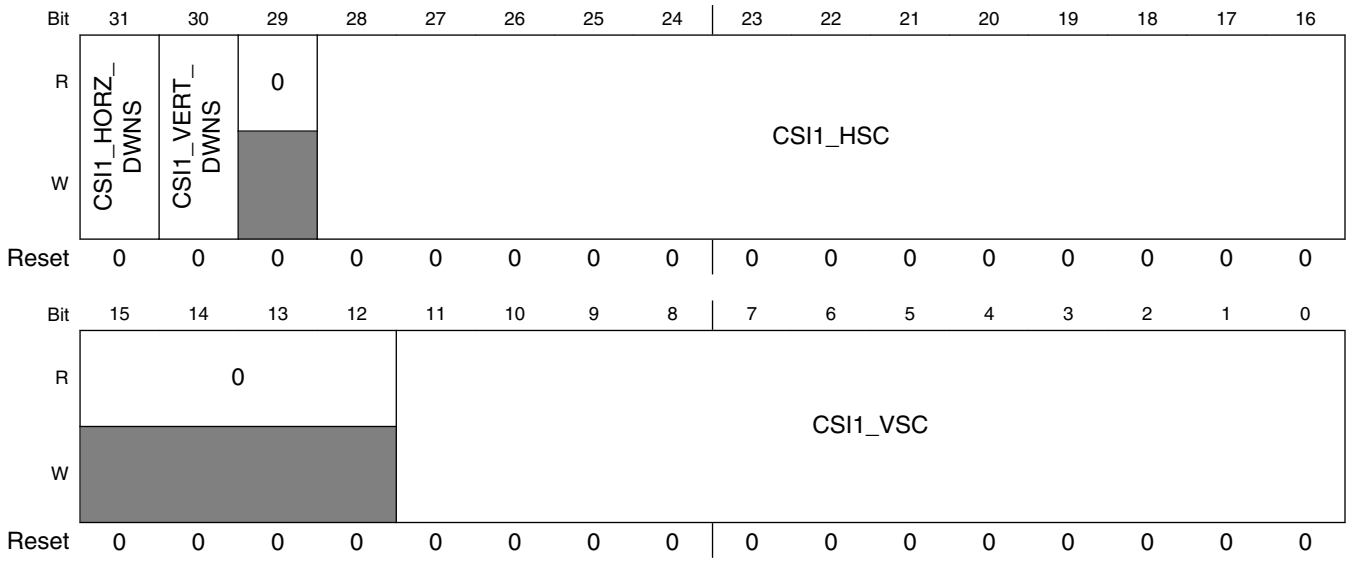
IPUx_CSI1_ACT_FRM_SIZE field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–16 CSI1_ACT_ FRM_HEIGHT	Actual frame height minus 1. This field defines the CSI output frame rows number minus 1.
15–13 Reserved	This read-only field is reserved and always has the value 0.
CSI1_ACT_ FRM_WIDTH	Actual frame width minus 1. This field defines the CSI output frame columns number minus 1.

37.5.175 CSI1 Output Control Register (IPUx_CSI1_OUT_FRM_CTRL)

Address: Base address + 3_800Ch offset

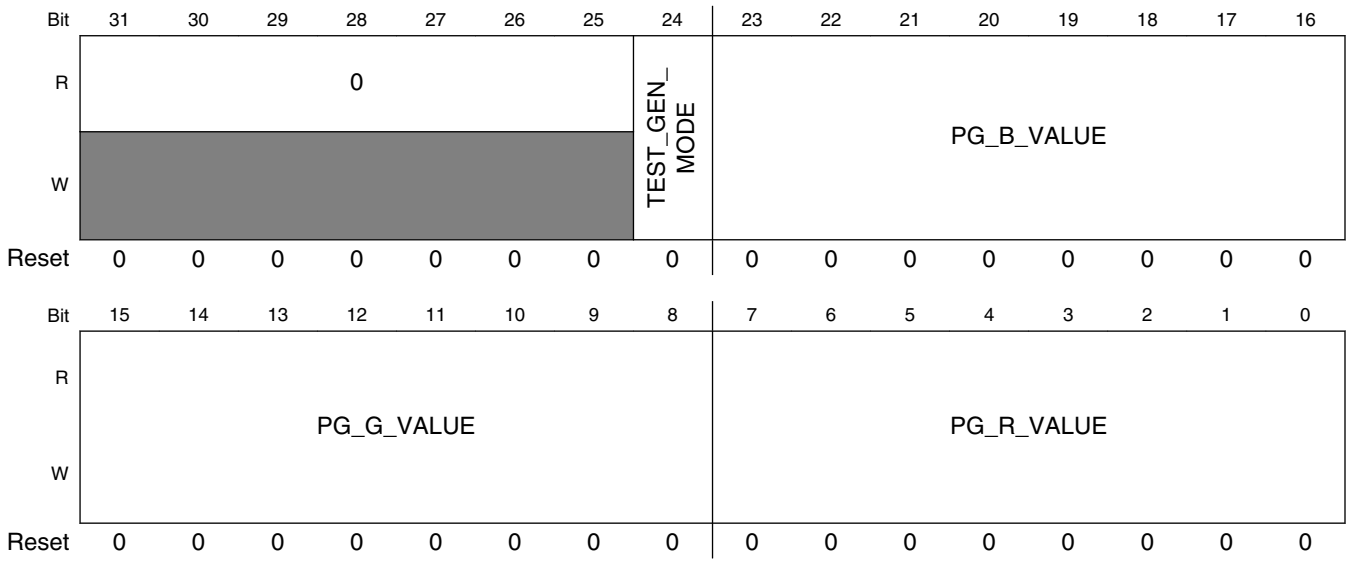


IPUx_CSI1_OUT_FRM_CTRL field descriptions

Field	Description
31 CSI1_HORZ_DWNS	Enable horizontal downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
30 CSI1_VERT_DWNS	Enable vertical downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
29 Reserved	This read-only field is reserved and always has the value 0.
28–16 CSI1_HSC	Horizontal skip. This field defines the number of columns to skip. In Interlaced mode this number refers to the number of lines per field
15–12 Reserved	This read-only field is reserved and always has the value 0.
CSI1_VSC	Vertical skip. This field defines the number of rows to skip.

37.5.176 CSI1 Test Control Register (IPUx_CSI1_TST_CTRL)

Address: Base address + 3_8010h offset

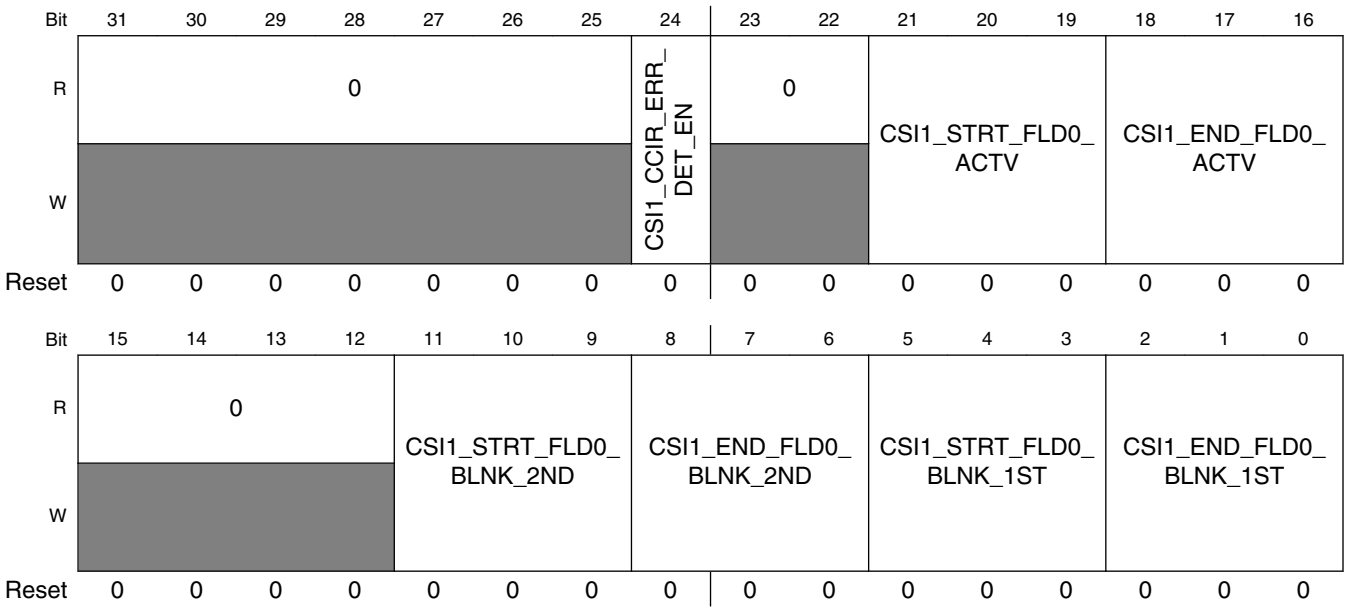


IPUx_CSI1_TST_CTRL field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 TEST_GEN_ MODE	Test generator mode. This bit activates the signal generation. 0 Test signal generator is inactive. 1 Test signal generator is active.
23–16 PG_B_VALUE	Pattern generator B value. This field selects the B value for the generated pattern of even pixel.
15–8 PG_G_VALUE	Pattern generator G value. This field selects the G value for the generated pattern of even pixel.
PG_R_VALUE	Pattern generator R value. This field selects the R value for the generated pattern of even pixel.

37.5.177 CSI1 CCIR Code Register 1 (IPUx_CSI1_CCIR_CODE_1)

Address: Base address + 3_8014h offset



IPUx_CSI1_CCIR_CODE_1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 CSI1_CCIR_ERR_DET_EN	Enable error detection and correction for CCIR interlaced mode with protection bit. 0 Error detection and correction is disabled. 1 Error detection and correction is enabled.
23–22 Reserved	This read-only field is reserved and always has the value 0.
21–19 CSI1_STRT_FLD0_ACTV	Start of field 0 active line command (interlaces mode). (In progressive mode, start of active line command mode).
18–16 CSI1_END_FLD0_ACTV	End of field 0 active line command (interlaces mode). (In progressive mode, end of active line command mode).
15–12 Reserved	This read-only field is reserved and always has the value 0.
11–9 CSI1_STRT_FLD0_BLNK_2ND	Start of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).
8–6 CSI1_END_FLD0_BLNK_2ND	End of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).

Table continues on the next page...

IPUx_CSI1_CCIR_CODE_1 field descriptions (continued)

Field	Description
5–3 CSI1_STRT_ FLD0_BLNK_ 1ST	Start of field 0 first blanking line command (interlaces mode). (In progressive mode this field indicates start of blanking line command).
CSI1_END_ FLD0_BLNK_ 1ST	End of field 0 first blanking line command (interlaces mode). (In progressive mode this field is ignored).

37.5.178 CSI1 CCIR Code Register 2 (IPUx_CSI1_CCIR_CODE_2)

Address: Base address + 3_8018h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

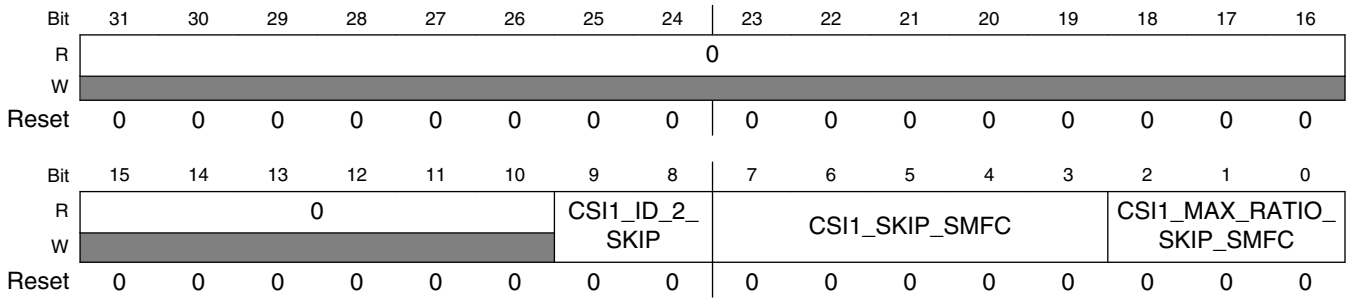
31–24 CSI1_MIPI_DI3	CSI1_MIPI_DI3 This field holds the Data Identifier #3 handled by the CSI.
23–16 CSI1_MIPI_DI2	CSI1_MIPI_DI2 This field holds the Data Identifier #2 handled by the CSI.
15–8 CSI0_MIPI_DI1	CSI1_MIPI_DI1 This field holds the Data Identifier #1 handled by the CSI
CSI1_MIPI_DI0	CSI1_MIPI_DI0 This field holds the Data Identifier #0 handled by the CSI; This is the main stream.

37.5.181 CSI1 SKIP Register (IPUx_CSI1_SKIP)

This register control the frame skipping supported between CSI1 and the SMFC.

Address: Base address + 3_8024h offset



IPUx_CSI1_SKIP field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 CSI1_ID_2_SKIP	CSI1 to SMFC Skipping ID. Data from the CSI1 to the SMFC has an ID associated with it. The ID is received from the MIPI interface. The skipping mechanism between the CSI1 and the SMFC can be used for only one ID. There is no skipping for data coming with ID different from the ID programed in this bits 00 - Skipping mechanism is activated on frames with ID equal to 00 01 - Skipping mechanism is activated on frames with ID equal to 01 10 - Skipping mechanism is activated on frames with ID equal to 10 11 - Skipping mechanism is activated on frames with ID equal to 11
7–3 CSI1_SKIP_SMFC	CSI1 SKIP SMFC These 5 bits define the skipping pattern of the frames send to the SMFC. Skipping is done for a set of frames. The number of frames in a set is defined at CSI1_MAX_RATIO_SKIP_SMFC. when CSI1_MAX_RATIO_SKIP_SMFC = 1 => CSI1_SKIP_SMFC[0] is used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 2 => CSI1_SKIP_SMFC[1:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 3 => CSI1_SKIP_SMFC[2:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 4 => CSI1_SKIP_SMFC[3:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 5 => CSI1_SKIP_SMFC[4:0] are used; Setting bit #n of CSI1_SKIP_SMFC means that the #n frame in the set is skipped. For example: if CSI1_MAX_RATIO_SKIP_SMFC = 4 and CSI1_SKIP_SMFC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI1_MAX_RATIO_SKIP_SMFC is set to 4

Table continues on the next page...

IPUx_CSI1_SKIP field descriptions (continued)

Field	Description
CSI1_MAX_ RATIO_SKIP_ SMFC	CSI1 Maximum Ratio Skip for SMFC These bits define the number of frames in a skipping set. These bits define the number of frames in a skipping set. The skipping number is equal to CSI1_MAX_RATIO_SKIP_SMFC+1; The maximum value of this bits is 5. When set to 0 the skipping is disabled.

37.5.182 CSI1 Compander Control Register (IPUx_CSI1_CPD_CTRL)

Address: Base address + 3_8028h offset

IPUx_DI0_GENERAL field descriptions

Field	Description
31 di0_pin8_pin15_sel	This bit routes PIN8 over PIN15 1 PIN8 is routed to PIN15, PIN8 is also routed to PIN8 0 PIN15 is routed to PIN15, PIN8 is routed to PIN8
30–28 di0_disp_y_sel	DI0 Display Vertical coordinate (Y) select. This field defines which one of the 8 counters will be used as a display's line counter. 000 counter #1 is selected 111 counter #8 is selected
27–24 DI0_CLOCK_STOP_MODE	DI clock stop mode When performing a clock change. The DI stops the clock to the display. These field defines when the clock will be stopped. Stopping at EOL/EOF is supported for the case where the data is coming from the IDMAC (DMA access). In case that only direct accesses is performed, the user should set this field to 0000 0001-1001 stop at the next event of one of the counters (counter #1 to counter #9) 0000 stop at the next edge of the display clock 1100 stop at EOL (end of a line), but if stop request is during blanking interval, stop now 1101 stop at EOF (end of a frame), but if stop request is during blanking interval, stop now 1110 stop at EOL (end of a line), but if stop request is during blanking interval, stop at the end of the next line 1111 stop at EOF (end of a frame), but if stop request is during blanking interval, stop at the end of the next frame

Table continues on the next page...

IPUx_DI0_GENERAL field descriptions (continued)

Field	Description
23 DI0_DISP_CLOCK_INIT	Display clock's initial mode For synchronization error conditions the display clock can be stopped on the next VSYNC 1 The display's clock is running after the next VSYNC (indicating new frame) 0 The display's clock is stopped after the next VSYNC (indicating new frame)
22 di0_mask_sel	DI0 Mask select. IPP_PIN_2 output of the DI that functions as MASK signal can come from 2 sources: counter #2 or extracted from the MASK data coming from the memory. 1 IPP_PIN_2 is coming from extracted MASK data coming from the memory 0 IPP_PIN_2 is coming from counter #2
21 di0_vsync_ext	DI0 External VSYNC. This bit selects the source of the VSYNC signal 1 External to the IPU 0 Internally generated by the IPU
20 di0_clk_ext	DI0 External Clock. This bit selects the source of the DI0's clock 1 The source of the clock is external to the IPU 0 The clock is internally generated by the IPU
19–18 DI0_WATCHDOG_MODE	DI0 watchdog mode In case of a display error where the DI clock is stopped (defined at di0_err_treatment). An internal watchdog counts DI clocks. If this timer reached its pre defined value the DI will skip the current frame and restart on the frame. This 2 bits define the number of DI clock cycles that the timer counts. 00 The timer counts 4 DI cycles 01 The timer counts 16 DI cycles 10 The timer counts 64 DI cycles 11 The timer counts 128 DI cycles
17 di0_polarity_disp_clk	DI0 Output Clock's polarity This bits define the polarity of the DI0's clock. 1 The output clock is active high 0 The output clock is active low
16 Reserved	This read-only field is reserved and always has the value 0.
15–12 di0_sync_count_sel	For synchronous flow error: selects synchronous flow synchronization counter in DI:
11 di0_err_treatment	In case of synchronous flow error there are 2 ways to handle the display 1 to wait (stop clock) 0 Drive the last component
10 di0_erm_vsync_sel	DI0 error recovery block's VSYNC source select The error recovery block detect a case where the DI's VSYNC is asserted before the EOF. This bit selects the source of the VSYNC signal monitored by this mechanism.

Table continues on the next page...

IPUx_DI0_GENERAL field descriptions (continued)

Field	Description
	1 vsync_post - an internal VSYNC signal asserted 2 lines after the DI's VSYNC 0 vsync_pre - an internal VSYNC signal asserted 2 lines before the DI's VSYNC
9 di0_polarity_cs1	DI0 Chip Select's 1 polarity This bits define the polarity of the DI's CS1. 1 The CS1 is active high 0 The CS1 is active low
8 di0_polarity_cs0	DI0 Chip Select's 0 polarity This bits define the polarity of the DI's CS0. 1 The CS0 is active high 0 The CS0 is active low
di0_polarity_i_1	DI0 output pin's polarity This bits define the polarity of each of the DI's outputs. 1 The output pin is active high 0 The output pin is active low

37.5.194 DI0 Base Sync Clock Gen 0 Register (IPUx_DI0_BS_CLKGEN0)

Address: Base address + 4_0004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

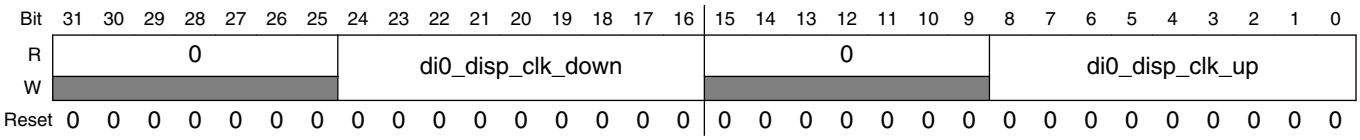
IPUx_DI0_BS_CLKGEN0 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24–16 di0_disp_clk_offset	DI0 Display Clock Offset The DI has the ability to delay the display's clock This field defines the amount of IPU's clock cycles added as delay on this clock.
15–12 Reserved	This read-only field is reserved and always has the value 0.
di0_disp_clk_period	DI0 Display Clock Period This field defines the Display interface clock period for display write access. This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the HSP_CLK clock for generation of the display's interface clock.

37.5.195 DI0 Base Sync Clock Gen 1 Register (IPUx_DI0_BS_CLKGEN1)

Address: Base address + 4_0008h offset

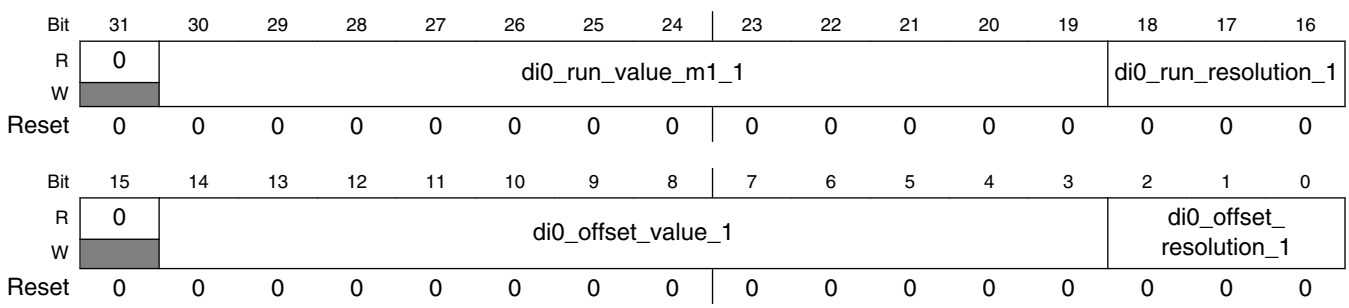


IPUx_DI0_BS_CLKGEN1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24–16 di0_disp_clk_down	DI0 display clock falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is a time interval between display's access start point and display's interface clock falling edge.
15–9 Reserved	This read-only field is reserved and always has the value 0.
di0_disp_clk_up	DI0 display clock rising edge position This parameter contains an integer part (bits 8:1) and a fractional part (bit 0). The position value is a time interval between display's access start point and display's interface clock rising edge.

37.5.196 DI0 Sync Wave Gen 1 Register 0 (IPUx_DI0_SW_GEN0_1)

Address: Base address + 4_000Ch offset



IPUx_DI0_SW_GEN0_1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

IPUx_DI0_SW_GEN0_1 field descriptions (continued)

Field	Description
30–19 di0_run_value_m1_1	DI0 counter #1 pre defined value This fields defines the counter #1 pre defines value. When the counter is auto reload mode (di0_cnt_auto_reload_1 bit is set), the counter automatically restarts. otherwise the counter restarts for the amount of time defined on the corresponding di0_step_repeat field.
18–16 di0_run_resolution_1	DI0 counter #1 Run Resolution This field defines the trigger causing the counter to increment. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSIs according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
15 Reserved	This read-only field is reserved and always has the value 0.
14–3 di0_offset_value_1	DI0 counter #1 offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by
di0_offset_resolution_1	DI0 counter #1 offset Resolution This field defines the trigger causing the offset counter to increment 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSIs according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.

The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
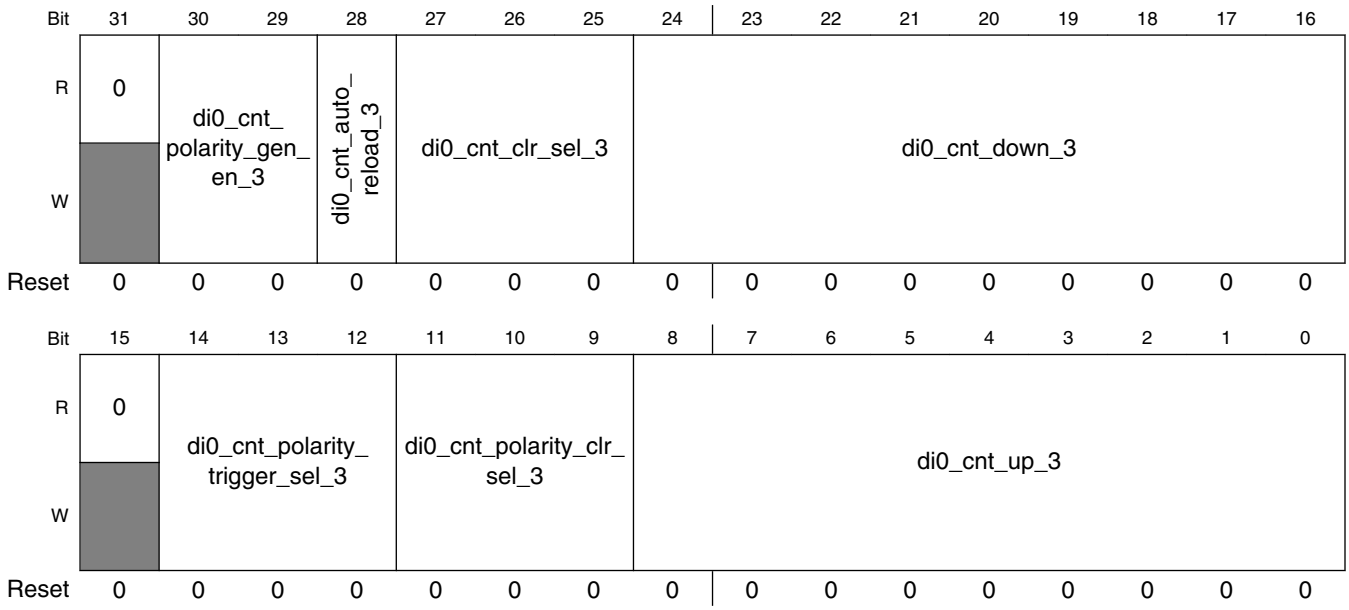
11–9 di0_cnt_polarity_clr_sel_2	DI0 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 Output is always inverted 001 Output is kept the same (no inversion) 010 Reserved 011 Reserved 100 Reserved 101 Reserved 110 Reserved 111 Reserved
di0_cnt_up_2	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

37.5.207 DI0 Sync Wave Gen 3 Register 1 (IPUx_DI0_SW_GEN1_3)

Address: Base address + 4_0038h offset



IPUx_DI0_SW_GEN1_3 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–29 di0_cnt_polarity_gen_en_3	DI0 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di0_cnt_auto_reload_3	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_<i> field
27–25 di0_cnt_clr_sel_3	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1

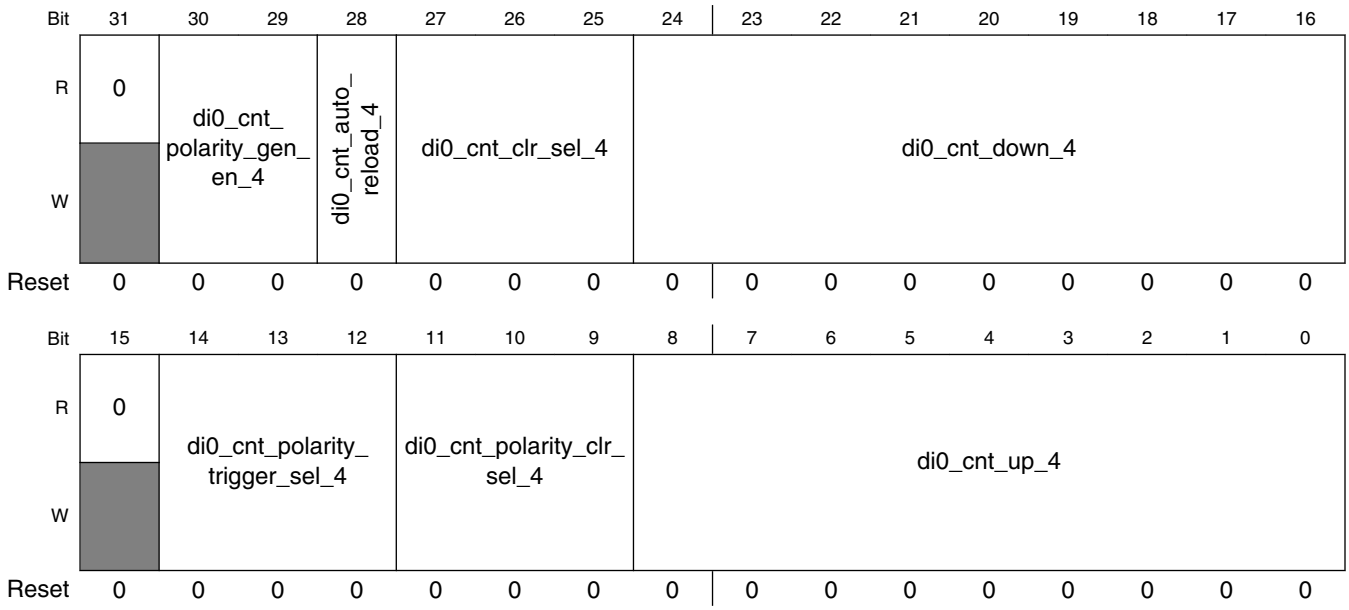
Table continues on the next page...

IPUx_DI0_SW_GEN1_3 field descriptions (continued)

Field	Description
	011 The Counter is triggered by counter #2 100 Reserved 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
24–16 di0_cnt_down_3	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 di0_cnt_polarity_trigger_sel_3	DI0 Counter's toggling trigger select This field selects the counter's trigger causing the output to toggle 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1 011 The Counter is triggered by counter #2 100 Reserved 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
11–9 di0_cnt_polarity_clr_sel_3	DI0 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 Output is always inverted 001 Output is kept the same (no inversion) 010 Output is inverted if the output of counter #1 is set 011 Output is inverted if the output of counter #2 is set 100 Reserved 101 Reserved 110 Reserved 111 Reserved
di0_cnt_up_3	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

37.5.208 DI0 Sync Wave Gen 4 Register 1 (IPUx_DI0_SW_GEN1_4)

Address: Base address + 4_003Ch offset



IPUx_DI0_SW_GEN1_4 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–29 di0_cnt_polarity_gen_en_4	DI0 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di0_cnt_auto_reload_4	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_<i> field
27–25 di0_cnt_clr_sel_4	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1

Field	Description
	011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.
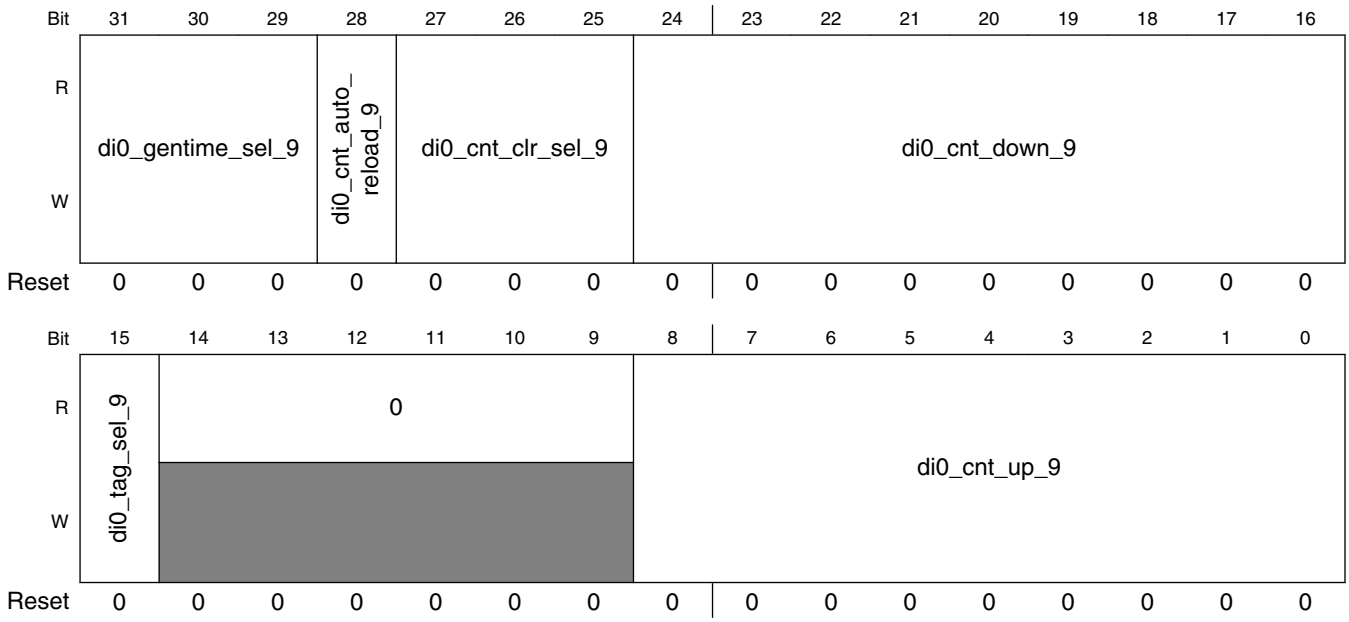
24–16 di0_cnt_down_8	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 di0_cnt_polarity_trigger_sel_8	DI0 Counter's toggling trigger select This field selects the counter's trigger causing the output to toggle 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1 011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.
11–9 di0_cnt_polarity_clr_sel_8	DI0 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 Output is always inverted 001 Output is kept the same (no inversion) 010 Output is inverted if the output of counter #1 is set 011 Output is inverted if the output of counter #2 is set 100 Output is inverted if the output of counter #3 is set 101 Output is inverted if the output of counter #4 is set 110 Output is inverted if the output of counter #5 is set 111 Output is inverted if the output of counter #6 is set
di0_cnt_up_8	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

37.5.213 DI0 Sync Wave Gen 9 Register 1 (IPUx_DI0_SW_GEN1_9)

Address: Base address + 4_0050h offset



IPUx_DI0_SW_GEN1_9 field descriptions

Field	Description
31–29 di0_gentime_sel_9	Counter #9 main waveform select This field defines the counter that counter #9's auxiliary waveform will be attached too. 000 Counter #9's waveform is attached to counter #1's waveform 001 Counter #9's waveform is attached to counter #2's waveform 010 Counter #9's waveform is attached to counter #3's waveform 011 Counter #9's waveform is attached to counter #4's waveform 100 Counter #9's waveform is attached to counter #5's waveform 101 Counter #9's waveform is attached to counter #6's waveform 110 Counter #9's waveform is attached to counter #7's waveform 111 Counter #9's waveform is attached to counter #8's waveform
28 di0_cnt_auto_reload_9	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_<i> field
27–25 di0_cnt_clr_sel_9	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1

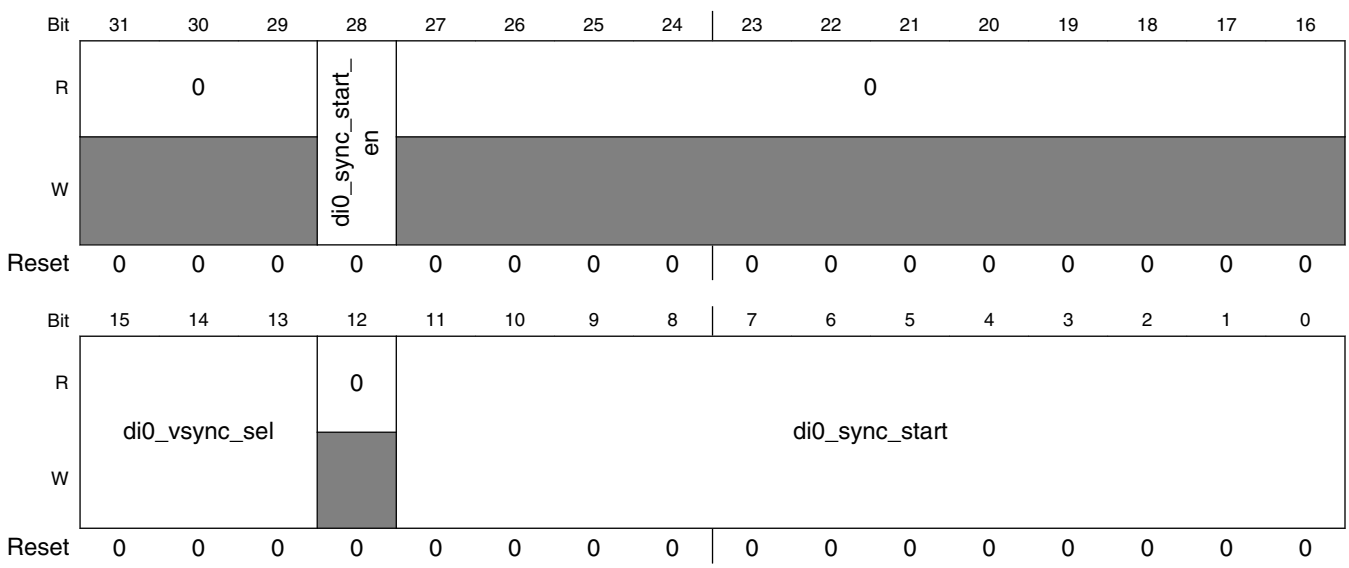
Table continues on the next page...

IPUx_DI0_SW_GEN1_9 field descriptions (continued)

Field	Description
	011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.
24–16 di0_cnt_down_9	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 di0_tag_sel_9	Counter #9 can send a synchronous tag when counter #9 reach its predefined value or when it's triggering counter reaches its pre defined value. 1 tag source is counter #9 0 Tag's source is the triggering counter.
14–9 Reserved	This read-only field is reserved and always has the value 0.
di0_cnt_up_9	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

37.5.214 DI0 Sync Assistance Gen Register (IPUx_DI0_SYNC_AS_GEN)

Address: Base address + 4_0054h offset



IPUx_DI0_SYNC_AS_GEN field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 di0_sync_start_en	di0_sync_start_en
27–16 Reserved	This read-only field is reserved and always has the value 0.
15–13 di0_vsync_sel	VSYNC select This field defines which of the counters functions as VSYNC signal 000 VSYNC is coming from counter #1 001 VSYNC is coming from counter #2 111 VSYNC is coming from counter #8
12 Reserved	This read-only field is reserved and always has the value 0.
di0_sync_start	DI0 Sync start This field defines the number of low (including blanking rows) on the which the DI0 starts preparing the data for the next frame.

37.5.215 DI0 Data Wave Gen <i> Register (IPUx_DI0_DW_GEN_i)

The DI0_DW_GEN_<i> register holds pointers for the waveform generators.

These registers have different bit arrangements for parallel and serial display. When using a parallel display VDI Plane Size Register 4 is applicable. When using a serial interface VDI Plane Size Register 4 is applicable.

Table 37-40. Register Field Descriptions for Serial Display

Field	Description
31-24 di0_serial_period_<i>	DI0 Serial Period <i> This field defines the period of the time base serial display clock. The units are the internal DI clock
23-16 di0_start_period_<i>	DI0 start period This field defines the amount of cycles between the point where the access is ready to be launched to the actual point where the time base serial display clock restarts. The units are the internal DI clock
15-14 di0_cst_<i>	DI0 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. For serial displays the down value as defined on DI0_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI0_DW_SET0_<i> 01 The waveform is defined according to the settings on DI0_DW_SET1_<i>

Table continues on the next page...

Table 37-40. Register Field Descriptions for Serial Display (continued)

Field	Description
	10 The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 The waveform is defined according to the settings on DI0_DW_SET3_<i>
13-9	Reserved
8-4 di0_serial_valid_bits<i>	DI0 Serial valid bits. This field defines the amount of valid bits to be transmitted within the 32 bits internal word aligned to bit[0]. The actual amount of valid bits is di0_serial_valid_bits_<i> + 1
3-2 di0_serial_rs_<i>	DI0 Serial RS This field points to a register that defines the waveform of the RS pin. For serial displays the down value as defined on DI0_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI0_DW_SET0_<i> 01 The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 The waveform is defined according to the settings on DI0_DW_SET3_<i>
1-0 di0_serial_clk_<i>	DI0 serial clock<i> This field points to a register that defines the waveform of the Serial clock pin. 00 The waveform is defined according to the settings on DI0_DW_SET0_<i> 01 The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 The waveform is defined according to the settings on DI0_DW_SET3_<i>

15–8 DI0_SERIAL_LATCH	DI0 Serial Latch This field defines how many cycles to insert between serial read accesses start to data sampling in the
7–6 Reserved	This read-only field is reserved and always has the value 0.

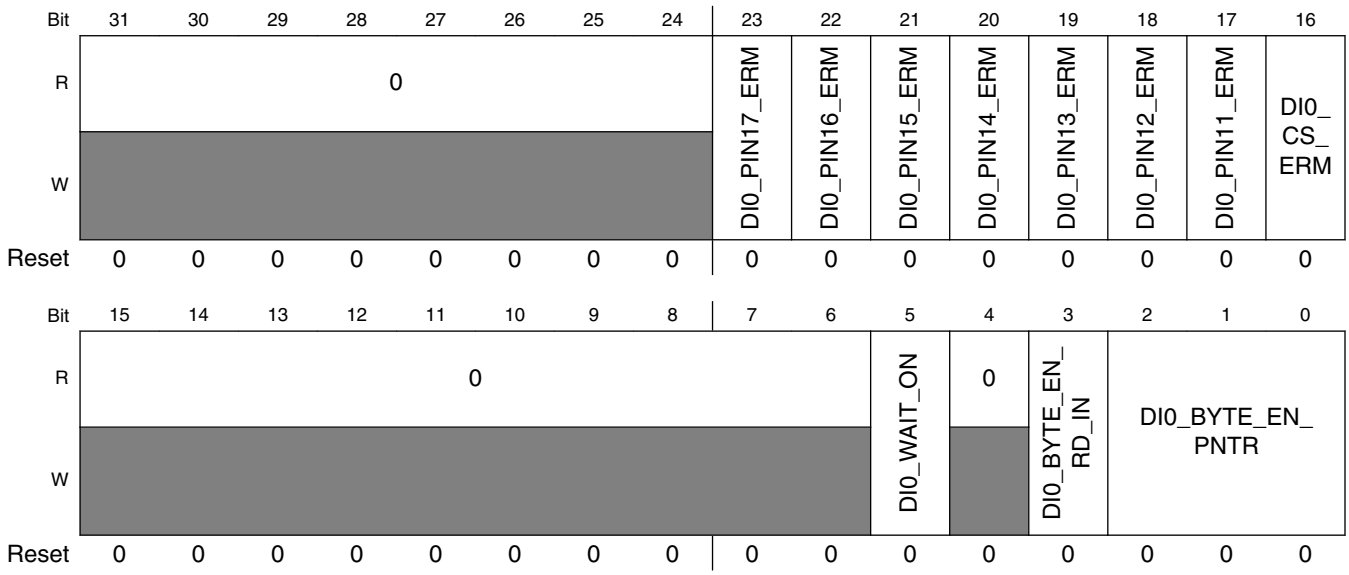
Table continues on the next page...

IPUx_DI0_SER_CONF field descriptions (continued)

Field	Description
5 DI0_LLA_SER_ACCESS	Direct Low Level Access to Serial display 1 ARM platform access is performed via a direct path to the serial display in LLA mode, in this mode only the ARM platform in LLA mode can access the serial port 0 ARM platform access to the serial display port is not done directly, hence other source are allowed to access the serial port. The arbitration is done automatically
4 DI0_SER_CLK_POLARITY	Serial Clock Polarity The output polarity of the SER_CLK pin 1 The clock is inverted 0 The clock is not inverted
3 DI0_SERIAL_DATA_POLARITY	Serial Data Polarity The output polarity of the SER_DATA pin 1 The data is inverted 0 The data is not inverted
2 DI0_SERIAL_RS_POLARITY	Serial RS Polarity The output polarity of the SER_RS pin 1 The RS is inverted 0 The RS is not inverted
1 DI0_SERIAL_CS_POLARITY	Serial Chip Select Polarity The output polarity of the SER_CS pin 1 The CS is inverted 0 The CS is not inverted
0 DI0_WAIT4SERIAL	Wait for Serial When the parallel display share pins with the serial port. Accessing the parallel port is not allowed till the serial port completes its access. 1 The parallel port should wait to the serial port as the pins are shared 0 The parallel port should not wait to the serial port as the pins are not shared

37.5.223 DI0 Special Signals Control Register (IPUx_DI0_SSC)

Address: Base address + 4_0160h offset



IPUx_DI0_SSC field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 DI0_PIN17_ERM	DI0 PIN17 error recovery mode. This bit defines the error recovery mode of the PIN17 pin. 1 The PIN17 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN17 pin following a display error detection
22 DI0_PIN16_ERM	DI0 PIN16 error recovery mode. This bit defines the error recovery mode of the PIN16 pin. 1 The PIN16 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN16 pin following a display error detection
21 DI0_PIN15_ERM	DI0 PIN15 error recovery mode. This bit defines the error recovery mode of the PIN15 pin. 1 The PIN15 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN15 pin following a display error detection
20 DI0_PIN14_ERM	DI0 PIN14 error recovery mode. This bit defines the error recovery mode of the PIN14 pin.

Table continues on the next page...

IPUx_DI0_SSC field descriptions (continued)

Field	Description
	1 The PIN14 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN14 pin following a display error detection
19 DI0_PIN13_ERM	DI0 PIN13 error recovery mode. This bit defines the error recovery mode of the PIN13 pin. 1 The PIN13 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN13 pin following a display error detection
18 DI0_PIN12_ERM	DI0 PIN12 error recovery mode. This bit defines the error recovery mode of the PIN12 pin. 1 The PIN12 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN12 pin following a display error detection
17 DI0_PIN11_ERM	DI0 PIN11 error recovery mode. This bit defines the error recovery mode of the PIN11 pin. 1 The PIN11 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN11 pin following a display error detection
16 DI0_CS_ERM	DI0 GLUELOGIC error recovery mode. This bit defines the error recovery mode of the GLUELOGIC. 1 The GLUELOGIC is release in case of a synchronous display error. The release will be done on the next VSYNC 0 Nothing is done to the GLUELOGIC following a display error detection
15–6 Reserved	This read-only field is reserved and always has the value 0.
5 DI0_WAIT_ON	Wait On This field defines the DC's response to WAIT signal 1 The DC holds the flow as long as WAIT is asserted 0 The DC continues the flow regardless the WAIT signal
4 Reserved	This read-only field is reserved and always has the value 0.
3 DI0_BYTE_EN_RD_IN	Byte Enable Read In This bit selects the source of the byte enable pins 1 The write byte enable signals are routed via bits [17:16] of the display's data, The read byte enable signals are routed via bits [19:18 of the display's data 0 The byte enable signals are routed via bits [17:16] of the display's data for both read and write
DI0_BYTE_EN_PNTR	Byte Enable Pointer This pointer selects the pin asserted along with the byte enables signals 000 wave form of byte enable as pin_11

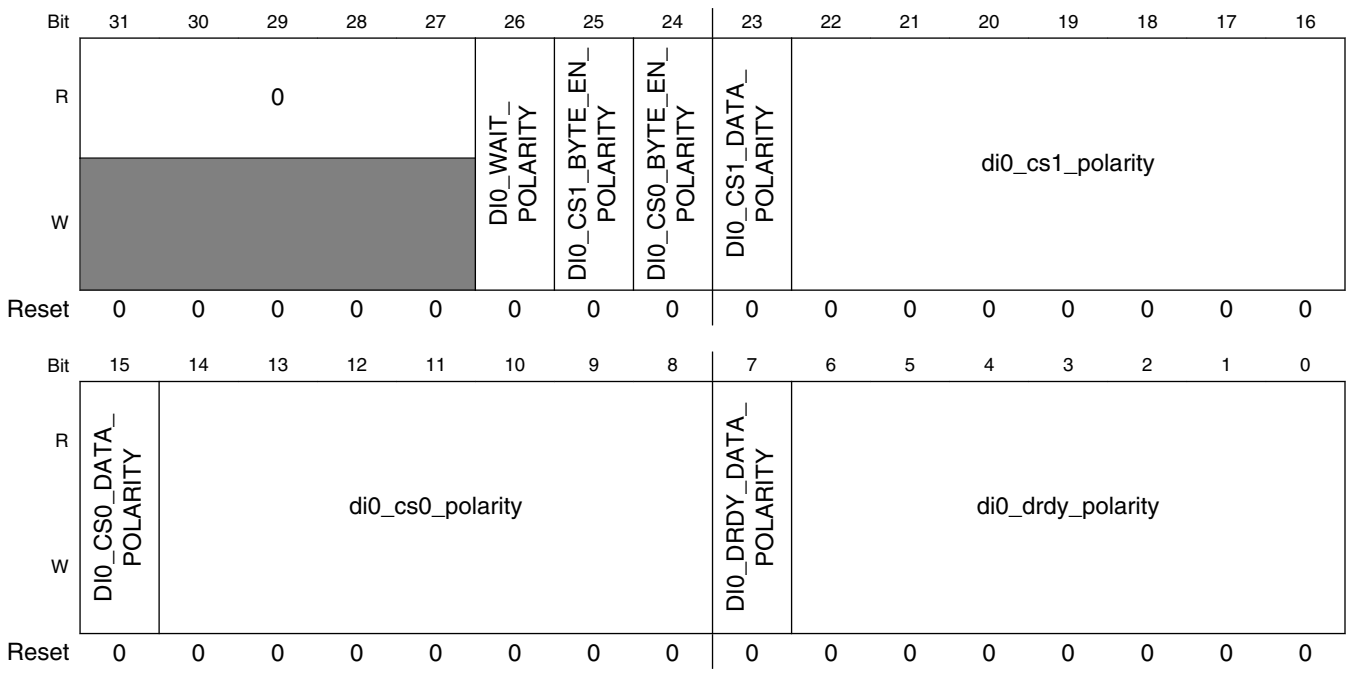
Table continues on the next page...

IPUx_DI0_SSC field descriptions (continued)

Field	Description
	001 wave form of byte enable as pin_12 111 wave form of byte enable as suitable CS pin

37.5.224 DI0 Polarity Register (IPUx_DI0_POL)

Address: Base address + 4_0164h offset



IPUx_DI0_POL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value 0.
26 DI0_WAIT_POLARITY	WAIT polarity This bit defines the polarity of the wait signal input coming from the displa1 1 active high 0 active low
25 DI0_CS1_BYTE_EN_POLARITY	Byte Enable associated with CS1 polarity This bit defines the polarity of the byte enable signals to the display 1 active high 0 active low
24 DI0_CS0_BYTE_EN_POLARITY	Byte Enable associated with CS0 polarity This bit defines the polarity of the byte enable signals to the display

Table continues on the next page...

IPUx_DI0_POL field descriptions (continued)

Field	Description
	1 active high 0 active low
23 DI0_CS1_DATA_POLARITY	Data Polarity associated with CS1
22–16 di0_cs1_polarity	DI0 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
15 DI0_CS0_DATA_POLARITY	Data Polarity associated with CS0
14–8 di0_cs0_polarity	DI0 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
7 DI0_DRDY_DATA_POLARITY	Data Polarity associated with DRDY
di0_drdy_polarity	DI0 output dynamic pin's polarity for synchronous access This bits define the polarity of each of the DI's outputs when synchronous display access is asserted The pins' default polarity is the same as defined in the di0_drdy_polarity bits 1 The output pin is active high 0 The output pin is active low

37.5.225 DI0 Active Window 0 Register (IPUx_DI0_AW0)

Address: Base address + 4_0168h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_DI1_GENERAL field descriptions

Field	Description
31 di1_pin8_pin15_sel	This bit routes PIN8 over PIN15 1 PIN8 is routed to PIN15, PIN8 is also routed to PIN8 0 PIN15 is routed to PIN15, PIN8 is routed to PIN8
30–28 di1_disp_y_sel	DI1 Display Vertical coordinate (Y) select. This field defines which one of the 8 counters will be used as a display's line counter. 000 counter #1 is selected 111 counter #8 is selected
27–24 DI1_CLOCK_STOP_MODE	DI clock stop mode When performing a clock change. The DI stops the clock to the display. These field defines when the clock will be stopped Stopping at EOL/EOF is supported for the case where the data is coming from the IDMAC (DMA access). In case that only direct accesses is performed, the user should set this field to 0000 0001-1001 stop at the next event of one of the counters (counter #1 to counter #9) 0000 stop at the next edge of the display clock 1100 stop at EOL (end of a line), but if stop request is during blanking interval, stop now 1101 stop at EOF (end of a frame), but if stop request is during blanking interval, stop now 1110 stop at EOL (end of a line), but if stop request is during blanking interval, stop at the end of the next line 1111 stop at EOF (end of a frame), but if stop request is during blanking interval, stop at the end of the next frame

Table continues on the next page...

IPUx_DI1_GENERAL field descriptions (continued)

Field	Description
23 DI1_DISP_CLOCK_INIT	Display clock's initial mode For synchronization error conditions the display clock can be stopped on the next VSYNC 1 The display's clock is running after the next VSYNC (indicating new frame) 0 The display's clock is stopped after the next VSYNC (indicating new frame)
22 di1_mask_sel	DI1 Mask select. IPP_PIN_2 output of the DI that functions as MASK signal can come from 2 sources: counter #2 or extracted from the MASK data coming from the memory. 1 IPP_PIN_2 is coming from extracted MASK data coming from the memory 0 IPP_PIN_2 is coming from counter #2
21 di1_vsync_ext	DI1 External VSYNC. This bit selects the source of the VSYNC signal 1 External to the IPU 0 Internally generated by the IPU
20 di1_clk_ext	DI1 External Clock. This bit selects the source of the DI's clock 1 The source of the clock is external to the IPU 0 The clock is internally generated by the IPU
19–18 DI1_WATCHDOG_MODE	DI1 watchdog mode In case of a display error where the DI clock is stopped (defined at di0_err_treatment). An internal watchdog counts DI clocks. If this timer reached its pre defined value the DI will skip the current frame and restart on the frame. This 2 bits define the number of DI clock cycles that the timer counts. 00 The timer counts 4 DI cycles 01 The timer counts 16 DI cycles 10 The timer counts 64 DI cycles 11 The timer counts 128 DI cycles
17 di1_polarity_disp_clk	DI1 Output Clock's polarity This bits define the polarity of the DI's clock. 1 The output clock is active high 0 The output clock is active low
16 Reserved	This read-only field is reserved and always has the value 0.
15–12 di1_sync_count_sel	For synchronous flow error: selects synchronous flow synchronization counter in DI:
11 di1_err_treatment	In case of synchronous flow error there are 2 ways to handle the display 1 to wait (i.e. stop clock) 0 Drive the last component
10 di1_erm_vsync_sel	DI1 error recovery module's VSYNC source select The error recovery block detect a case where the DI's VSYNC is asserted before the EOF. This bit selects the source of the VSYNC signal monitored by this mechanism.

Table continues on the next page...

IPUx_DI1_GENERAL field descriptions (continued)

Field	Description
	1 vsync_post - an internal VSYNC signal asserted 2 lines after the DI's VSYNC 0 vsync_pre - an internal VSYNC signal asserted 2 lines before the DI's VSYNC
9 di1_polarity_cs1	DI1 Chip Select's 1 polarity This bits define the polarity of the DI's CS1. 1 The CS1 is active high 0 The CS1 is active low
8 di1_polarity_cs0	DI1 Chip Select's 0 polarity This bits define the polarity of the DI's CS0. 1 The CS0 is active high 0 The CS0 is active low
di1_polarity_i_1	DI1 output pin's polarity This bits define the polarity of each of the DI's outputs. 1 The output pin is active high 0 The output pin is active low

37.5.230 DI1 Base Sync Clock Gen 0 Register (IPUx_DI1_BS_CLKGEN0)

Address: Base address + 4_8004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

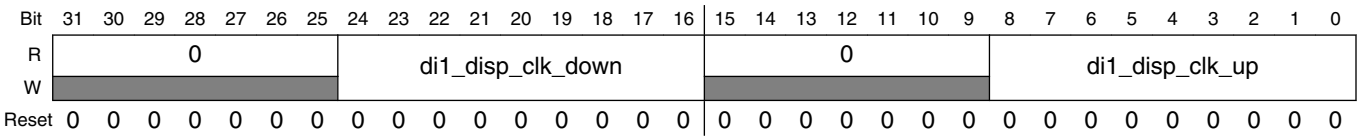
IPUx_DI1_BS_CLKGEN0 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24–16 di1_disp_clk_offset	DI1 Display Clock Offset The DI has the ability to delay the display's clock This field defines the amount of IPU's clock cycles added as delay on this clock.
15–12 Reserved	This read-only field is reserved and always has the value 0.
di1_disp_clk_period	DI1 Display Clock Period This field defines the Display interface clock period for display write access. This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the HSP_CLK clock for generation of the display's interface clock.

37.5.231 DI1 Base Sync Clock Gen 1 Register (IPUx_DI1_BS_CLKGEN1)

Address: Base address + 4_8008h offset

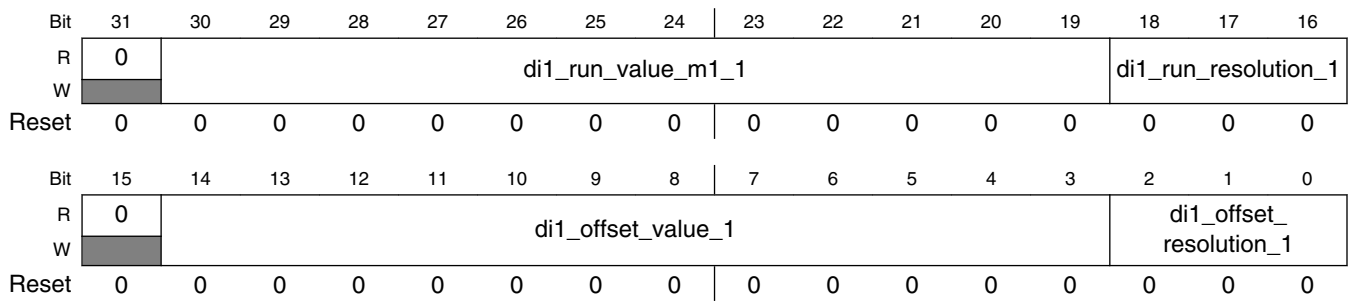


IPUx_DI1_BS_CLKGEN1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24–16 di1_disp_clk_down	DI1 display clock falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is a time interval between display's access start point and display 's interface clock falling edge.
15–9 Reserved	This read-only field is reserved and always has the value 0.
di1_disp_clk_up	DI1 display clock rising edge position This parameter contains an integer part (bits 8:1) and a fractional part (bit 0). The position value is a time interval between display's access start point and display 's interface clock rising edge.

37.5.232 DI1 Sync Wave Gen 1 Register 0 (IPUx_DI1_SW_GEN0_1)

Address: Base address + 4_800Ch offset



IPUx_DI1_SW_GEN0_1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

IPUx_DI1_SW_GEN0_1 field descriptions (continued)

Field	Description
30–19 di1_run_value_m1_1	DI1 counter #1 pre defined value This fields defines the counter #1 pre defines value. When the counter is auto reload mode (di1_cnt_auto_reload_1 bit is set), the counter automatically restarts. otherwise the counter restarts for the amount of time defined on the corresponding di1_step_repeat field.
18–16 di1_run_resolution_1	DI1 counter #1 Run Resolution This field defines the trigger causing the counter to increment. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
15 Reserved	This read-only field is reserved and always has the value 0.
14–3 di1_offset_value_1	DI1 counter #1 offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by
di1_offset_resolution_1	DI1 counter #1 offset Resolution This field defines the trigger causing the offset counter to increment 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.

Field	Description
	011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.
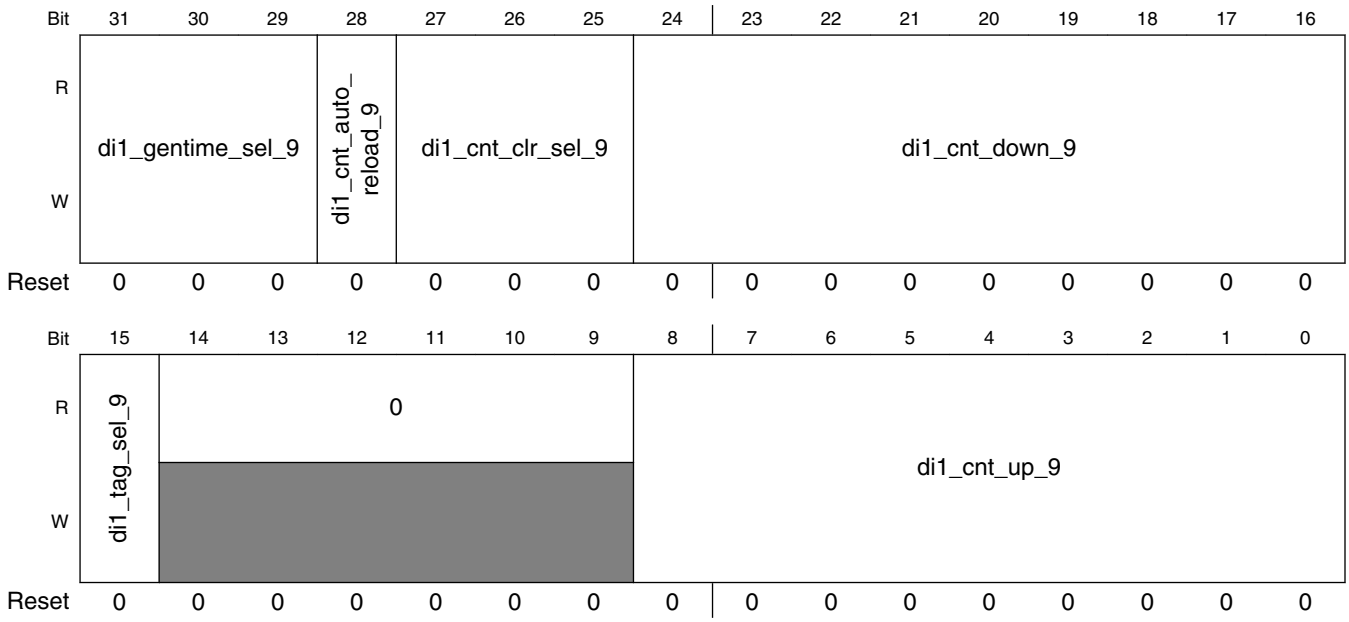
24–16 di1_cnt_down_8	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 di1_cnt_polarity_trigger_sel_8	DI1 Counter's toggling trigger select This field selects the counter's trigger causing the output to toggle 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1 011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.
11–9 di1_cnt_polarity_clr_sel_8	DI1 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 Output is always inverted 001 Output is kept the same (no inversion) 010 Output is inverted if the output of counter #1 is set 011 Output is inverted if the output of counter #2 is set 100 Output is inverted if the output of counter #3 is set 101 Output is inverted if the output of counter #4 is set 110 Output is inverted if the output of counter #5 is set 111 Output is inverted if the output of counter #6 is set
di1_cnt_up_8	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

37.5.249 DI1 Sync Wave Gen 9 Register 1 (IPUx_DI1_SW_GEN1_9)

Address: Base address + 4_8050h offset



IPUx_DI1_SW_GEN1_9 field descriptions

Field	Description
31–29 di1_gentime_sel_9	Counter #9 main waveform select This field defines the counter that counter #9's auxiliary waveform will be attached too. 000 Counter #9's waveform is attached to counter #1's waveform 001 Counter #9's waveform is attached to counter #2's waveform 010 Counter #9's waveform is attached to counter #3's waveform 011 Counter #9's waveform is attached to counter #4's waveform 100 Counter #9's waveform is attached to counter #5's waveform 101 Counter #9's waveform is attached to counter #6's waveform 110 Counter #9's waveform is attached to counter #7's waveform 111 Counter #9's waveform is attached to counter #8's waveform
28 di1_cnt_auto_reload_9	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di1_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di1_step_repeat_<i> field
27–25 di1_cnt_clr_sel_9	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1

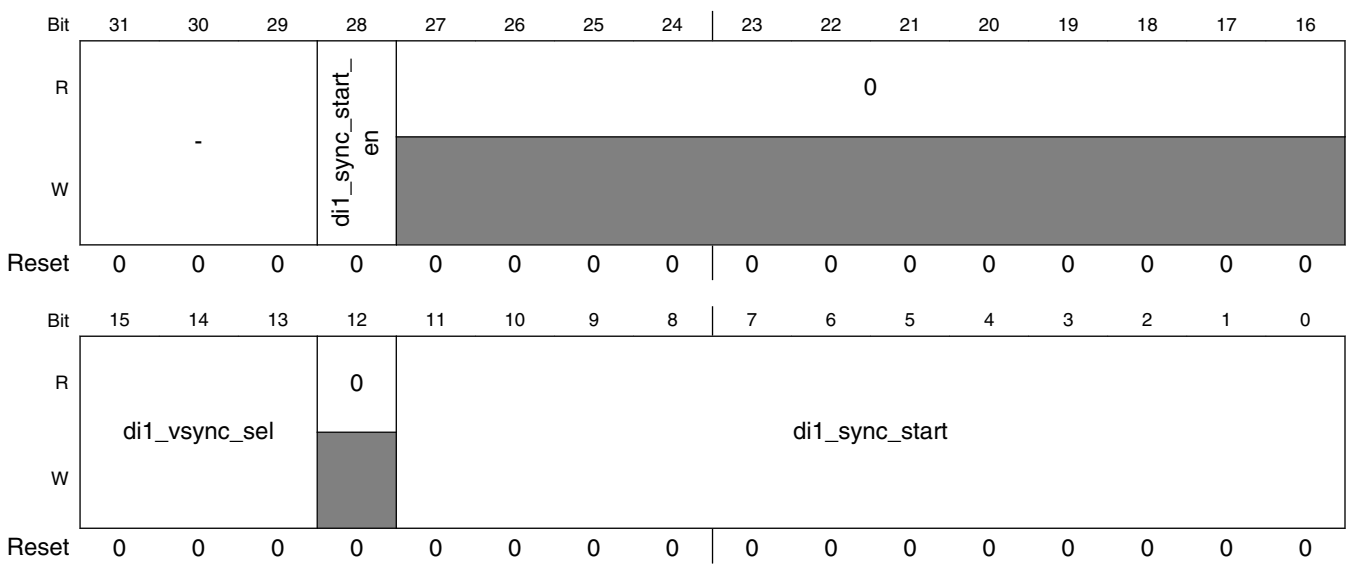
Table continues on the next page...

IPUx_DI1_SW_GEN1_9 field descriptions (continued)

Field	Description
	011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.
24–16 di1_cnt_down_9	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 di1_tag_sel_9	Counter #9 can send a synchronous tag when counter #9 reach its predefined value or when it's triggering counter reaches its pre defined value. 1 tag source is counter #9 0 Tag's source is the triggering counter.
14–9 Reserved	This read-only field is reserved and always has the value 0.
di1_cnt_up_9	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

37.5.250 DI1 Sync Assistance Gen Register (IPUx_DI1_SYNC_AS_GEN)

Address: Base address + 4_8054h offset



IPUx_DI1_SYNC_AS_GEN field descriptions

Field	Description
31–29 -	Reserve
28 di1_sync_start_en	di1_sync_start_en
27–16 Reserved	This read-only field is reserved and always has the value 0.
15–13 di1_vsync_sel	VSYNC select This field defines which of the counters functions as VSYNC signal 000 VSYNC is coming from counter #1 001 VSYNC is coming from counter #2 111 VSYNC is coming from counter #8
12 Reserved	This read-only field is reserved and always has the value 0.
di1_sync_start	DI1 Sync start This field defines the number of low (including blanking rows) on the which the DI1 starts preparing the data for the next frame.

37.5.251 DI1 Data Wave Gen <i> Register (IPUx_DI1_DW_GEN_i)

The DI1_DW_GEN_<i> register holds pointers for the waveform generators.

These registers have different bit arrangements for parallel and serial display. When using a parallel display VDI Plane Size Register 4 is applicable. When using a serial interface VDI Plane Size Register 4 is applicable.

Table 37-41. Register Field Descriptions for Serial display

Field	Description
31-24 di1_serial_period_<i>	DI1 Serial Period <i> This field defines the period of the time base serial display clock. The units are the internal DI clock
23-16 di1_start_period_<i>	DI1 start period This field defines the amount of cycles between the point where the access is ready to be launched to the actual point where the time base serial display clock restarts. The units are the internal DI clock.
15-14 di1_cst_<i>	DI1 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. For serial displays the down value as defined on DI1_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI1_DW_SET0_<i> 01 The waveform is defined according to the settings on DI1_DW_SET1_<i>

Table continues on the next page...

Table 37-41. Register Field Descriptions for Serial display (continued)

Field	Description
	10 The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 The waveform is defined according to the settings on DI1_DW_SET3_<i>
13-9	Reserved
8-4 di1_serial_valid_bits_<i>	DI1 Serial valid bits. This field defines the amount of valid bits to be transmitted within the 32 bits internal word aligned to bit[0]. The actual amount of valid bits is di1_serial_valid_bits_<i> + 1
3-2 di1_serial_rs_<i>	DI1 Serial RS This field points to a register that defines the waveform of the RS pin. For serial displays the down value as defined on DI1_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI1_DW_SET0_<i> 01 The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 The waveform is defined according to the settings on DI1_DW_SET3_<i>
1-0 di1_serial_clk_<i>	DI1 serial clock<i> This field points to a register that defines the waveform of the Serial clock pin. 00 The waveform is defined according to the settings on DI1_DW_SET0_<i> 01 The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 The waveform is defined according to the settings on DI1_DW_SET3_<i>

Field	Description
31–28 DI1_SERIAL_LLA_PNTR_RS_R_1	RS 3 waveform pointer for read low level access This pointer defines which waveform set will be chosen when the read low level access is targeted to RS group 1. 0000 Waveform set #1 0001 Waveform set #2 1011 Waveform set #12 1100 Reserved 1101 Reserved 1100 Reserved
27–24 DI1_SERIAL_LLA_PNTR_RS_R_0	RS 2 waveform pointer for low level access This pointer defines which waveform set will be chosen when the read low level access is targeted to RS group 0. 0000 Waveform set #1 0001 Waveform set #2 1011 Waveform set #12 1100 Reserved 1101 Reserved 1100 Reserved
23–20 DI1_SERIAL_LLA_PNTR_RS_W_1	RS 1 waveform pointer for write low level access This pointer defines which waveform set will be chosen when the write low level access is targeted to RS group 1. 0000 Waveform set #1 0001 Waveform set #2 1011 Waveform set #12 1100 Reserved 1101 Reserved 1100 Reserved
19–16 DI1_SERIAL_LLA_PNTR_RS_W_0	RS 0 waveform pointer for write low level access This pointer defines which waveform set will be chosen when the write low level access is targeted to RS group 0. 0000 Waveform set #1 0001 Waveform set #2 1011 Waveform set #12 1100 Reserved 1101 Reserved 1100 Reserved
15–8 DI1_SERIAL_LATCH	DI1 Serial Latch This field defines how many cycles to insert between serial read accesses start to data sampling in the
7–6 Reserved	This read-only field is reserved and always has the value 0.

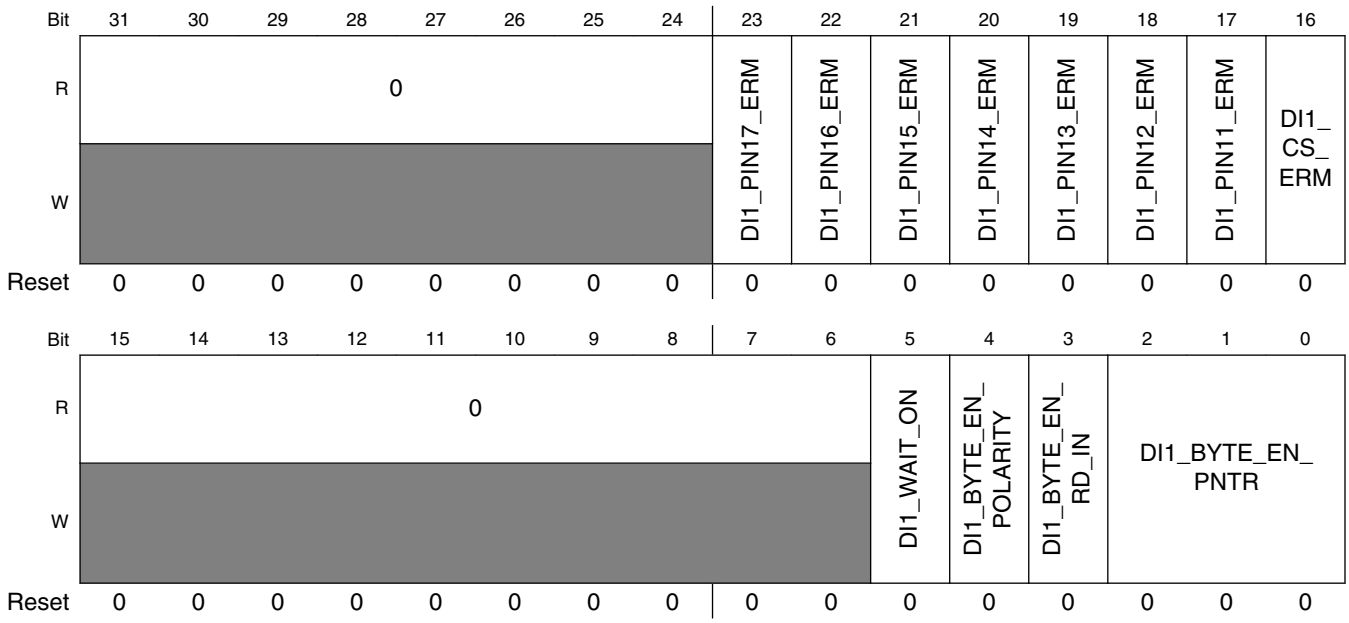
Table continues on the next page...

IPUx_DI1_SER_CONF field descriptions (continued)

Field	Description
5 DI1_LLA_SER_ACCESS	Direct Low Level Access to Serial display 1 ARM platform access is performed via a direct path to the serial display in LLA mode, in this mode only the ARM platform in LLA mode can access the serial port 0 ARM platform access to the serial display port is not done directly, hence other source are allowed to access the serial port. The arbitration is done automatically
4 DI1_SER_CLK_POLARITY	Serial Clock Polarity The output polarity of the SER_CLK pin 1 The clock is inverted 0 The clock is not inverted
3 DI1_SERIAL_DATA_POLARITY	Serial Data Polarity The output polarity of the SER_DATA pin 1 The data is inverted 0 The data is not inverted
2 DI1_SERIAL_RS_POLARITY	Serial RS Polarity The output polarity of the SER_RS pin 1 The RS is inverted 0 The RS is not inverted
1 DI1_SERIAL_CS_POLARITY	Serial Chip Select Polarity The output polarity of the SER_CS pin 1 The CS is inverted 0 The CS is not inverted
0 DI1_WAIT4SERIAL	Wait for Serial When the parallel display share pins with the serial port. Accessing the parallel port is not allowed till the serial port completes its access. 1 The parallel port should wait to the serial port as the pins are shared 0 The parallel port should not wait to the serial port as the pins are not shared

37.5.259 DI1 Special Signals Control Register (IPUx_DI1_SSC)

Address: Base address + 4_8160h offset



IPUx_DI1_SSC field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 DI1_PIN17_ERM	DI1 PIN17 error recovery mode. This bit defines the error recovery mode of the PIN17 pin. 1 The PIN17 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN17 pin following a display error detection.
22 DI1_PIN16_ERM	DI1 PIN16 error recovery mode. This bit defines the error recovery mode of the PIN16 pin. 1 The PIN16 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN16 pin following a display error detection.
21 DI1_PIN15_ERM	DI1 PIN15 error recovery mode. This bit defines the error recovery mode of the PIN15 pin. 1 The PIN15 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN15 pin following a display error detection.
20 DI1_PIN14_ERM	DI1 PIN14 error recovery mode. This bit defines the error recovery mode of the PIN14 pin.

Table continues on the next page...

IPUx_DI1_SSC field descriptions (continued)

Field	Description
	1 The PIN14 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN14 pin following a display error detection.
19 DI1_PIN13_ERM	DI1 PIN13 error recovery mode. This bit defines the error recovery mode of the PIN13 pin. 1 The PIN13 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN13 pin following a display error detection.
18 DI1_PIN12_ERM	DI1 PIN12 error recovery mode. This bit defines the error recovery mode of the PIN12 pin. 1 The PIN12 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN12 pin following a display error detection.
17 DI1_PIN11_ERM	DI1 PIN11 error recovery mode. This bit defines the error recovery mode of the PIN11 pin. 1 The PIN11 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN11 pin following a display error detection.
16 DI1_CS_ERM	DI1 GLUELOGIC error recovery mode. This bit defines the error recovery mode of the GLUELOGIC. 1 The GLUELOGIC is release in case of a synchronous display error. The release will be done on the next VSYNC. 0 Nothing is done to the GLUELOGIC following a display error detection.
15–6 Reserved	This read-only field is reserved and always has the value 0.
5 DI1_WAIT_ON	Wait On This field defines the DC's response to WAIT signal 1 The DC holds the flow as long as WAIT is asserted. 0 The DC continues the flow regardless the WAIT signal.
4 DI1_BYTE_EN_POLARITY	Byte Enable polarity This bit defines the polarity of the byte enable signals to the display. 1 active high. 0 active low.
3 DI1_BYTE_EN_RD_IN	Byte Enable Read In This bit selects the source of the byte enable pins 1 The write byte enable signals are routed via bits [17:16] of the display's data, The read byte enable signals are routed via bits [19:18 of the display's data 0 The byte enable signals are routed via bits [17:16] of the display's data for both read and write
DI1_BYTE_EN_PNTR	Byte Enable Pointer This pointer selects the pin asserted along with the byte enables signals

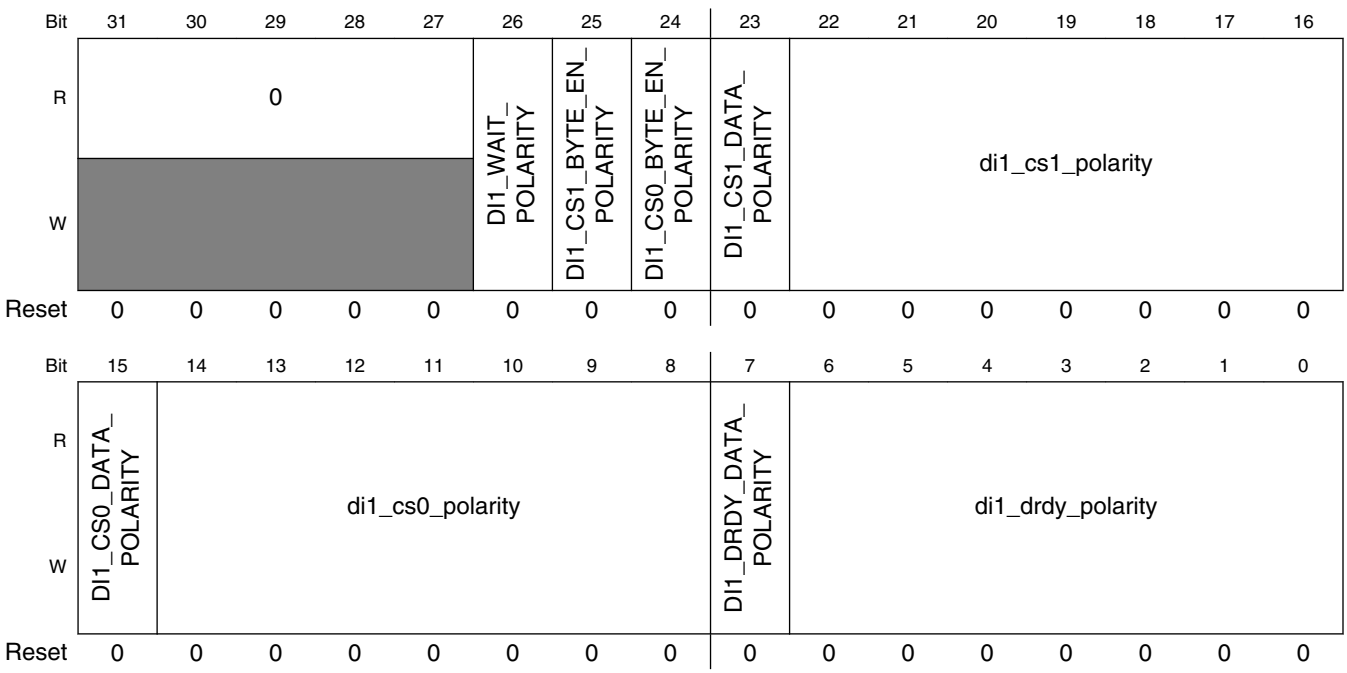
Field	Description
	000 wave form of byte enable as pin_11 001 wave form of byte enable as pin_12 111 wave form of byte enable as suitable CS pin

37.5.260 DI1 Polarity Register (IPUx_DI1_POL)

Address: Base address + 4_8164h offset



IPUx_DI1_POL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value 0.
26 DI1_WAIT_POLARITY	WAIT polarity This bit defines the polarity of the wait signal input coming from the displa1 1 active high 0 active low
25 DI1_CS1_BYTE_EN_POLARITY	Byte Enable associated with CS1 polarity This bit defines the polarity of the byte enable signals to the display 1 active high 0 active low

Table continues on the next page...

IPUx_DI1_POL field descriptions (continued)

Field	Description
24 DI1_CS0_BYTE_EN_POLARITY	Byte Enable associated with CS0 polarity This bit defines the polarity of the byte enable signals to the display 1 active high 0 active low
23 DI1_CS1_DATA_POLARITY	Data Polarity associated with CS1
22–16 di1_cs1_polarity	DI1 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
15 DI1_CS0_DATA_POLARITY	Data Polarity associated with CS0
14–8 di1_cs0_polarity	DI1 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
7 DI1_DRDY_DATA_POLARITY	Data Polarity associated with DRDY
di1_drdy_polarity	DI1 output dynamic pin's polarity for synchronous access This bits define the polarity of each of the DI's outputs when synchronous display access is asserted The pins' default polarity is the same as defined in the di0_drdy_polarity bits 1 The output pin is active high 0 The output pin is active low

37.5.261 DI1Active Window 0 Register (IPUx_DI1_AW0)

Address: Base address + 4_8168h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_DI1_STAT field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
3 DI1_CNTR_ FIFO_FULL	This bit indicates a full state of the DI1 FIFO. This FIFO is part of the DI1 synchronizer.
2 DI1_CNTR_ FIFO_EMPTY	This bit indicates an empty state of the DI1 FIFO. This FIFO is part of the DI1 synchronizer.
1 DI1_READ_ FIFO_FULL	This bit indicates a full state of the DI1 FIFO when performing a read. This FIFO is part of the DI1 synchronizer.
0 DI1_READ_ FIFO_EMPTY	This bit indicates an empty state of the DI1 FIFO when performing a read. This FIFO is part of the DI1 synchronizer.

37.5.265 SMFC Mapping Register (IPUx_SMFC_MAP)

The purpose of this register is to map CSI frames to IDMAC channels.

Address: Base address + 5_0000h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_SMFC_MAP field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value 0.
11–9 MAP_CH3	DMASMFC channel 3mapping bits. 000 CSI0, ID=0 mapped to DMASMFC channel 3. 001 CSI0, ID=1 mapped to DMASMFC channel 3. 010 CSI0, ID=2 mapped to DMASMFC channel 3. 011 CSI0, ID=3 mapped to DMASMFC channel 3. 100 CSI1, ID=0 mapped to DMASMFC channel 3. 101 CSI1, ID=1 mapped to DMASMFC channel 3. 110 CSI1, ID=2 mapped to DMASMFC channel 3. 111 CSI1, ID=3 mapped to DMASMFC channel 3.
8–6 MAP_CH2	DMASMFC channel 2 mapping bits. 000 CSI0, ID=0 mapped to DMASMFC channel 2.

Table continues on the next page...

IPUx_SMFC_MAP field descriptions (continued)

Field	Description
	001 CSI0, ID=1 mapped to DMASMFC channel 2. 010 CSI0, ID=2 mapped to DMASMFC channel 2. 011 CSI0, ID=3 mapped to DMASMFC channel 2. 100 CSI1, ID=0 mapped to DMASMFC channel 2. 101 CSI1, ID=1 mapped to DMASMFC channel 2. 110 CSI1, ID=2 mapped to DMASMFC channel 2. 111 CSI1, ID=3 mapped to DMASMFC channel 2.
5–3 MAP_CH1	DMASMFC channel 1 mapping bits. 000 CSI0, ID=0 mapped to DMASMFC channel 1. 001 CSI0, ID=1 mapped to DMASMFC channel 1. 010 CSI0, ID=2 mapped to DMASMFC channel 1. 011 CSI0, ID=3 mapped to DMASMFC channel 1. 100 CSI1, ID=0 mapped to DMASMFC channel 1. 101 CSI1, ID=1 mapped to DMASMFC channel 1. 110 CSI1, ID=2 mapped to DMASMFC channel 1. 111 CSI1, ID=3 mapped to DMASMFC channel 1.
MAP_CH0	DMASMFC channel 0 mapping bits. 000 CSI0, ID=0 mapped to DMASMFC channel 0. 001 CSI0, ID=1 mapped to DMASMFC channel 0. 010 CSI0, ID=2 mapped to DMASMFC channel 0. 011 CSI0, ID=3 mapped to DMASMFC channel 0. 100 CSI1, ID=0 mapped to DMASMFC channel 0. 101 CSI1, ID=1 mapped to DMASMFC channel 0. 110 CSI1, ID=2 mapped to DMASMFC channel 0. 111 CSI1, ID=3 mapped to DMASMFC channel 0.

37.5.266 SMFC Watermark Control Register (IPUx_SMFC_WMC)

The purpose of this register is to control watermarks levels of DMA channels. The bit setting given relative to FIFO size and not in number of words since FIFO size depend from number of enabled DMA channels.

Address: Base address + 5_0004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPUx_SMFC_WMC field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–25 WM3_CLR	Watermark "clear" level of DMASMFC channel 3. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.
24–22 WM3_SET	Watermark "set" level of DMASMFC channel 3 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.
21–19 WM2_CLR	Watermark "clear" level of DMASMFC channel 2. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.
18–16 WM2_SET	Watermark "set" level of DMASMFC channel 2. 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.
15–12 Reserved	This read-only field is reserved and always has the value 0.
11–9 WM1_CLR	Watermark "clear" level of DMASMFC channel 1. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.
8–6 WM1_SET	Watermark "set" level of DMASMFC channel 1. 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.
5–3 WM0_CLR	Watermark "clear" level of DMASMFC channel 0. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.
WM0_SET	Watermark "set" level of DMASMFC channel 0.

Table continues on the next page...

IPUx_SMFC_WMC field descriptions (continued)

Field	Description
	000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.

37.5.267 SMFC Burst Size Register (IPUx_SMFC_BS)

This register holds the burst size value for each DMASMFC channel. The burst size is the number of IDMAC's active accesses that will done for each IDMAC's burst. This number is a function of PFS, BPP & NPB parameters in the IDMAC's CPMEM. These are the parameters corresponding to the IDMAC's channel used. The table below describes what should be the burst size according to PFS, BPP & NPB settings

Table 37-42. SMFC Burst Size

BPP	PFS	BURST_SIZE
8	6	NPB[6:4]
16	6	NPB[6:3]
All other	All other	NPB[6:2]

Address: Base address + 5_0008h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPUx_SMFC_BS field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 BURST3_SIZE	Burst Size of SMFCDMA channel 3. The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)
11–8 BURST2_SIZE	Burst Size of SMFCDMA channel 2. The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)
7–4 BURST1_SIZE	Burst Size of SMFCDMA channel 1. The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)
BURST0_SIZE	Burst Size of SMFCDMA channel 0.

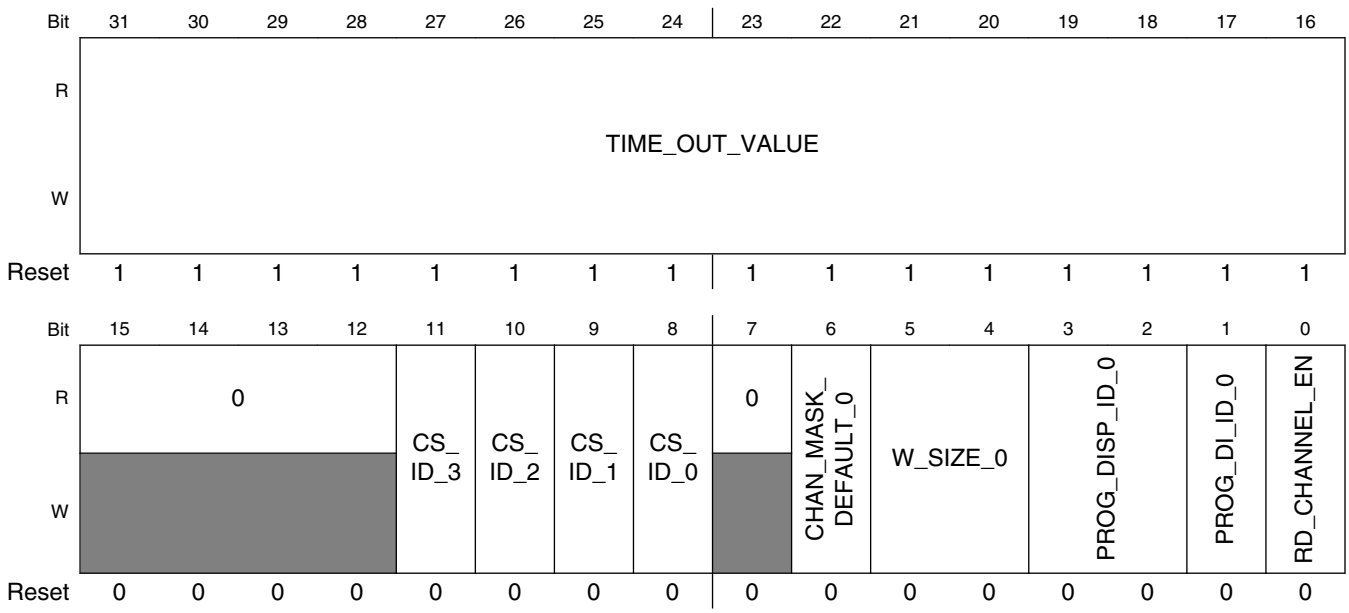
Table continues on the next page...

IPUx_SMFC_BS field descriptions (continued)

Field	Description
	The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)

37.5.268 DC Read Channel Configuration Register (IPUx_DC_READ_CH_CONF)

Address: Base address + 5_8000h offset



IPUx_DC_READ_CH_CONF field descriptions

Field	Description
31–16 TIME_OUT_ VALUE	Time out value. In case of a error during read accesses to the display, where no response from the display was received. A time-out counter will terminate the current access and perform the next commend defined in the microcode. This field defines the amount of the hsp_clk cycles counted before the time-out event is issued. This event is tied to the interrupt controller and can generate an error interrupt.
15–12 Reserved	This read-only field is reserved and always has the value 0.
11 CS_ID_3	This bit maps an asynchronous display to a chip select 1 display #3 is connected to CS1 0 display #3 is connected to CS0
10 CS_ID_2	This bit maps an asynchronous display to a chip select 1 display #2 is connected to CS1 0 display #2 is connected to CS0

Table continues on the next page...

IPUx_DC_READ_CH_CONF field descriptions (continued)

Field	Description
9 CS_ID_1	This bit maps an asynchronous display to a chip select 1 display #1 is connected to CS1 0 display #1 is connected to CS0
8 CS_ID_0	This bit maps an asynchronous display to a chip select 1 display #0 is connected to CS1 0 display #0 is connected to CS0
7 Reserved	This read-only field is reserved and always has the value 0.
6 CHAN_MASK_DEFAULT_0	Event mask bit for the read channel When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
5–4 W_SIZE_0	Word Size The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used
3–2 PROG_DISP_ID_0	The field defines which one of the 4 displays can be read. 00 display #0 01 display #1 10 display #2 11 display #3
1 PROG_DI_ID_0	This bit select the DI which a read transaction can be performed through 1 DI #1 0 DI #0
0 RD_CHANNEL_EN	This bit enables the read channel. 1 The Read channel is enabled 0 The Read channel is disabled

37.5.269 DC Read Channel Start Address Register (IPUx_DC_READ_SH_ADDR)

Address: Base address + 5_8004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

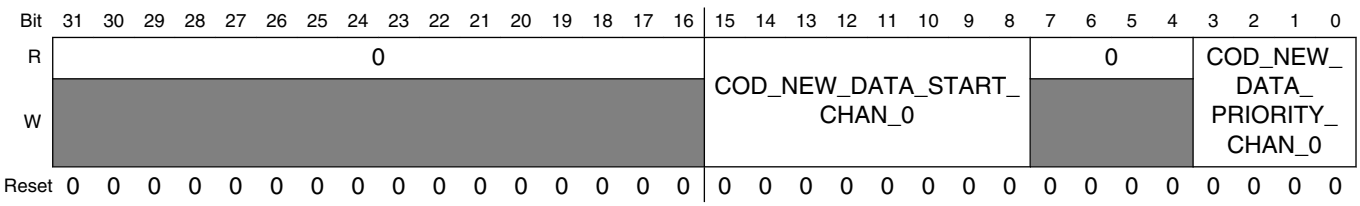
IPUx_DC_RL3_CH_0 field descriptions (continued)

Field	Description
	0001 Priority #1 (lowest) 0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved

37.5.274 DC Routine Link Register 4 Channel 0 (IPUx_DC_RL4_CH_0)

Address: Base address + 5_8018h offset

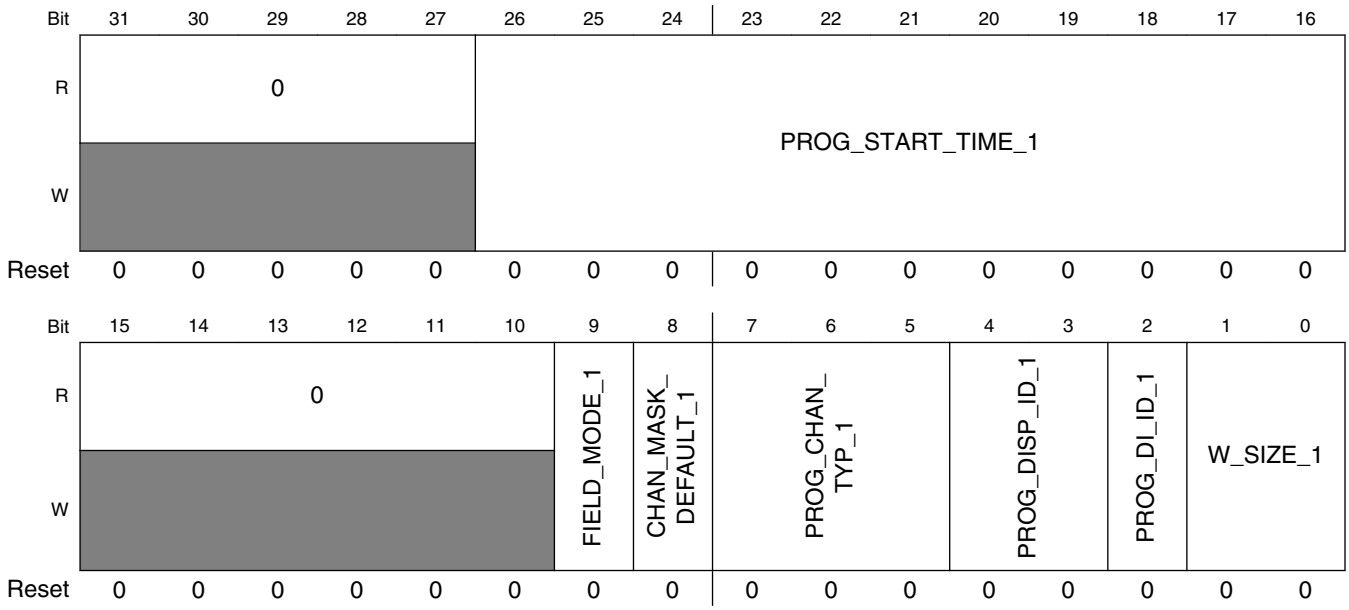


IPUx_DC_RL4_CH_0 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 COD_NEW_DATA_START_CHAN_0	This field is a pointer to the address within the microcode memory where the routine that handles the new data event resides
7–4 Reserved	This read-only field is reserved and always has the value 0.
COD_NEW_DATA_PRIORITY_CHAN_0	This field defines the priority of the new data event The priority between the events should be set to a unique value. i.e. two events must not have the same priority (except 0000 - disable) 0000 disable 0001 Priority #1 (lowest) 0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved

37.5.275 DC Write Channel 1 Configuration Register (IPUx_DC_WR_CH_CONF_1)

Address: Base address + 5_801Ch offset



IPUx_DC_WR_CH_CONF_1 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value 0.
26–16 PROG_START_TIME_1	This field defines the delay between display 's vertical synchronization pulse and the start time point of DC's channel 1 window. The delay is defined in pairs of rows. It is used for tearing elimination
15–10 Reserved	This read-only field is reserved and always has the value 0.
9 FIELD_MODE_1	Field mode bit for channel #1 This bit defines if the channel works in field mode or frame mode; This bit is relevant if the flow is sync flow 1 Field mode 0 Frame mode
8 CHAN_MASK_DEFAULT_1	Event mask bit for channel #1 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
7–5 PROG_CHAN_TYP_1	This field define the mode of operation of channel #1 000 Disable 001 Reserved

Table continues on the next page...

IPUx_DC_WR_CH_CONF_1 field descriptions (continued)

Field	Description
	010 Reserved 100 Normal mode without anti-tearing. For sync display this is the only mode allowed 101 Normal mode with anti-tearing 110 Reserved 111 Additional command channel is added to the flow handled by DC channel #1
4–3 PROG_DISP_ID_1	The field defines which one of the 4 displays is associated with channel #1. 00 display #0 01 display #1 10 display #2 11 display #3
2 PROG_DI_ID_1	This bit select the DI which a transaction associated with channel #1 can be performed to 1 DI #1 0 DI #0
W_SIZE_1	Word Size associated with channel #1 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

37.5.276 DC Write Channel 1 Address Configuration Register (IPUx_DC_WR_CH_ADDR_1)

Address: Base address + 5_8020h offset

IPUx_DC_CMD_CH_CONF_3 field descriptions

Field	Description
31–24 COD_CMND_START_CHAN_RS1_3	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #3); This field is relevant when RS is equal to 1
23–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 COD_CMND_START_CHAN_RS0_3	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #3); This field is relevant when RS is equal to 0
7–2 Reserved	This read-only field is reserved and always has the value 0.
W_SIZE_3	Word Size associated with channel #3 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

37.5.290 DC Command Channel 4 Configuration Register (IPUx_DC_CMD_CH_CONF_4)

Address: Base address + 5_8058h offset

IPUx_DC_CMD_CH_CONF_4 field descriptions

Field	Description
31–24 COD_CMND_START_CHAN_RS1_4	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #4); This field is relevant when RS is equal to 1
23–16 Reserved	This read-only field is reserved and always has the value 0.

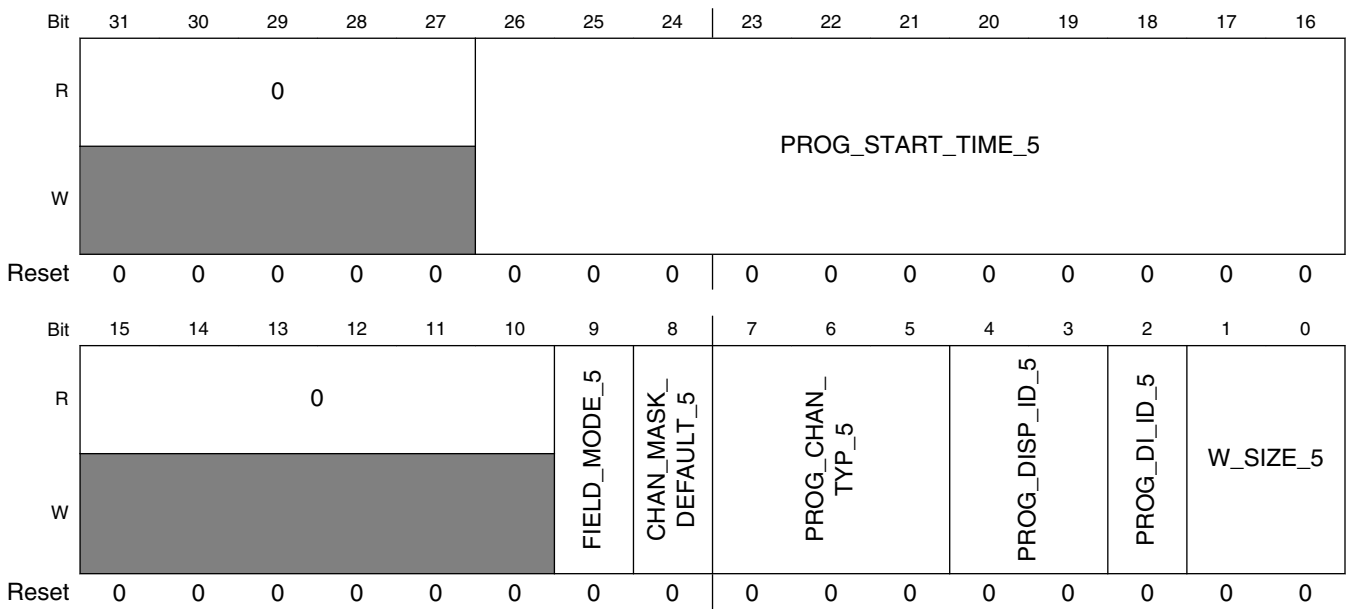
Table continues on the next page...

IPUx_DC_CMD_CH_CONF_4 field descriptions (continued)

Field	Description
15–8 COD_CMND_START_CHAN_RS0_4	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #4); This field is relevant when RS is equal to 0
7–2 Reserved	This read-only field is reserved and always has the value 0.
W_SIZE_4	Word Size associated with channel #4 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

37.5.291 DC Write Channel 5Configuration Register (IPUx_DC_WR_CH_CONF_5)

Address: Base address + 5_805Ch offset



IPUx_DC_WR_CH_CONF_5 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value 0.
26–16 PROG_START_TIME_5	This field defines the delay between display 's vertical synchronization pulse and the start time point of DC's channel 5 window. The delay is defined in pairs of rows. It is used for tearing elimination

Table continues on the next page...

IPUx_DC_WR_CH_CONF_5 field descriptions (continued)

Field	Description
15–10 Reserved	This read-only field is reserved and always has the value 0.
9 FIELD_MODE_5	Field mode bit for channel #5 This bit defines if the channel works in field mode or frame mode; This bit is relevant if the flow is sync flow 1 Field mode 0 Frame mode
8 CHAN_MASK_DEFAULT_5	Event mask bit for channel #5 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
7–5 PROG_CHAN_TYP_5	This field define the mode of operation of channel #5 000 Disable 001 Reserved 010 Reserved 100 Normal mode without anti-tearing. For sync display this is the only mode allowed 101 Normal mode with anti-tearing 110 Reserved 111 Additional command channel is added to the flow handled by DC channel #5
4–3 PROG_DISP_ID_5	The field defines which one of the 4 displays is associated with channel #5. 00 display #0 01 display #1 10 display #2 11 display #3
2 PROG_DI_ID_5	This bit select the DI which a transaction associated with channel #5 can be performed to. When channel 28 is connected to DI0, channel 23 must be connected to DI1 even if ch23 is not used. This is done by writing 1 to this bit. 1 DI #1 0 DI #0
W_SIZE_5	Word Size associated with channel #5 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

37.5.292 DC Write Channel 5Address Configuration Register (IPUx_DC_WR_CH_ADDR_5)

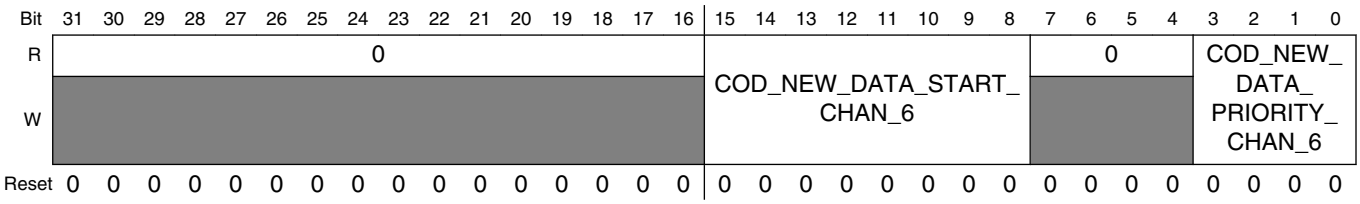
IPUx_DC_RL3_CH_6 field descriptions

Field	Description
31–24 COD_NEW_CHAN_START_CHAN_6	This field is a pointer to the address within the microcode memory where the routine that handles the new channel event resides (associated with channel #6)
23–20 Reserved	This read-only field is reserved and always has the value 0.
19–16 COD_NEW_CHAN_PRIORITY_CHAN_6	This field defines the priority of the new field event (associated with channel #6) The priority between the events should be set to a unique value. i.e. two events must not have the same priority (except 0000 - disable) 0000 disable 0001 Priority #1 (lowest) 0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved
15–8 COD_NEW_ADDR_START_CHAN_6	This field is a pointer to the address within the microcode memory where the routine that handles the new address event resides (associated with channel #6)
7–4 Reserved	This read-only field is reserved and always has the value 0.
COD_NEW_ADDR_PRIORITY_CHAN_6	This field defines the priority of the new field event (associated with channel #6) The priority between the events should be set to a unique value. i.e. two events must not have the same priority (except 0000 - disable) 0000 disable 0001 Priority #1 (lowest) 0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved

37.5.304 DC Routine Link Register 4 Channel 6 (IPUx_DC_RL4_CH_6)

Address: Base address + 5_8090h offset

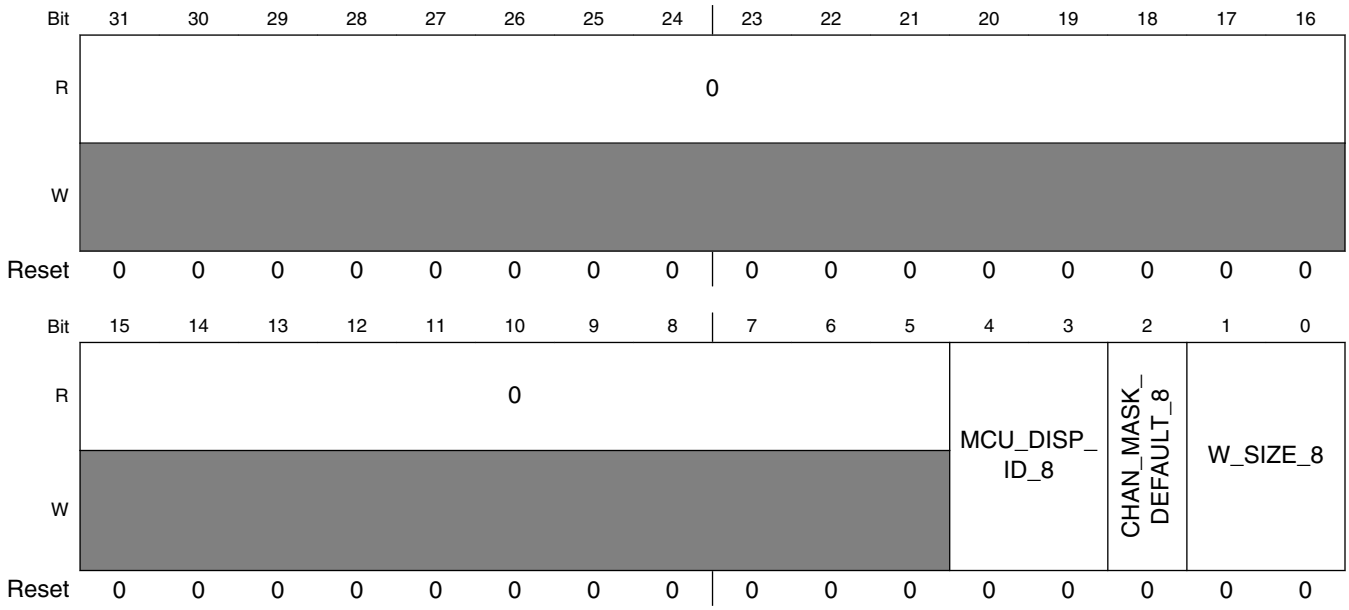


IPUx_DC_RL4_CH_6 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 COD_NEW_DATA_START_CHAN_6	This field is a pointer to the address within the microcode memory where the routine that handles the new data event resides (associated with channel #6)
7–4 Reserved	This read-only field is reserved and always has the value 0.
COD_NEW_DATA_PRIORITY_CHAN_6	This field defines the priority of the new field event (associated with channel #6) The priority between the events should be set to a unique value. i.e. two events must not have the same priority (except 0000 - disable) 0000 disable 0001 Priority #1 (lowest) 0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved

37.5.305 DC Write Channel 8 Configuration 1Register (IPUx_DC_WR_CH_CONF1_8)

Address: Base address + 5_8094h offset



IPUx_DC_WR_CH_CONF1_8 field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4–3 MCU_DISP_ID_8	The field defines which one of the 4 displays is associated with channel #8. 00 display #0 01 display #1 10 display #2 11 display #3
2 CHAN_MASK_DEFAULT_8	Event mask bit for channel #8 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
W_SIZE_8	Word Size associated with channel #8 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

37.5.306 DC Write Channel 8 Configuration 2 Register (IPUx_DC_WR_CH_CONF2_8)

Address: Base address + 5_8098h offset

37.5.320 DC Routine Link Register 6 Channel 9 (IPUx_DC_RL6_CH_9)

Address: Base address + 5_80D0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	COD_NEW_DATA_START_CHAN_R_9_1								0								COD_NEW_DATA_START_CHAN_R_9_0								0							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPUx_DC_RL6_CH_9 field descriptions

Field	Description
31–24 COD_NEW_DATA_START_CHAN_R_9_1	This field is a pointer to the address within the microcode memory where the routine that handles the new data event resides (associated with channel #9, second region)
23–16 Reserved	This read-only field is reserved and always has the value 0.

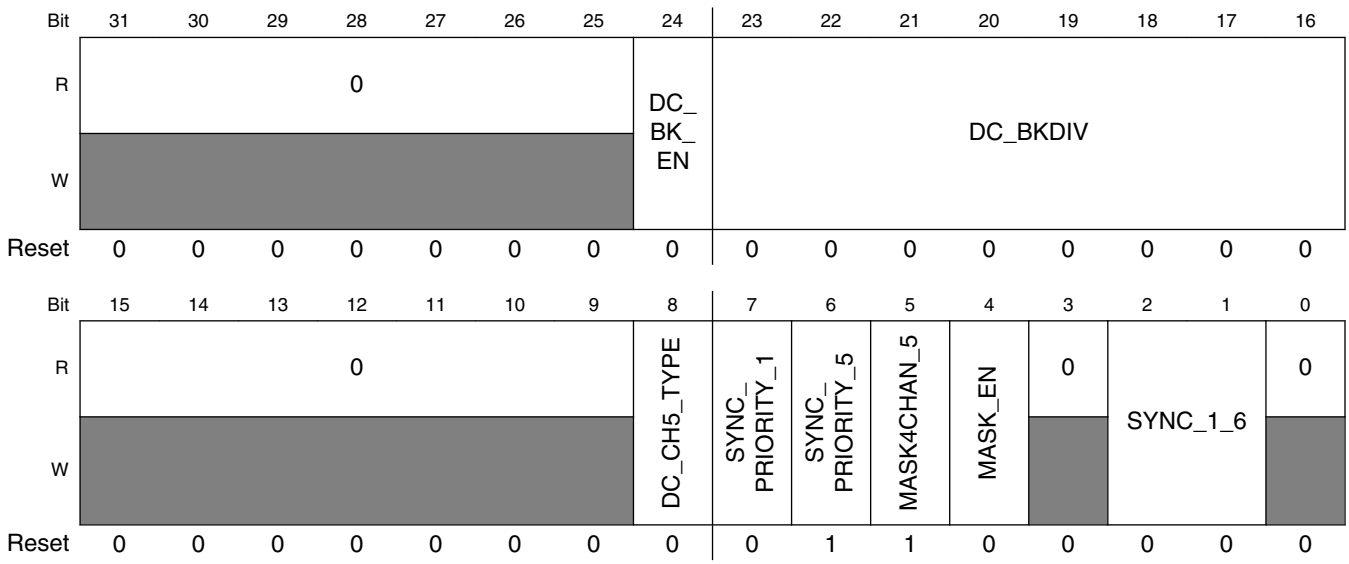
Table continues on the next page...

IPUx_DC_RL6_CH_9 field descriptions (continued)

Field	Description
15–8 COD_NEW_DATA_START_CHAN_R_9_0	This field is a pointer to the address within the microcode memory where the routine that handles the new data event resides (associated with channel #9, first region)
Reserved	This read-only field is reserved and always has the value 0.

37.5.321 DC General Register (IPUx_DC_GEN)

Address: Base address + 5_80D4h offset



IPUx_DC_GEN field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 DC_BK_EN	Cursor blinking enable 1 blinking is enabled 0 blinking is disabled
23–16 DC_BKDIV	Blinking Rate This field defines the blinking rate. The blinking occurs every N-th frame While N is defined by DC_BKDIV
15–9 Reserved	This read-only field is reserved and always has the value 0.
8 DC_CH5_TYPE	Channel 5 is used for synchronous flow. When this channel is used for accessing asynchronous display that is activated in a synchronous way

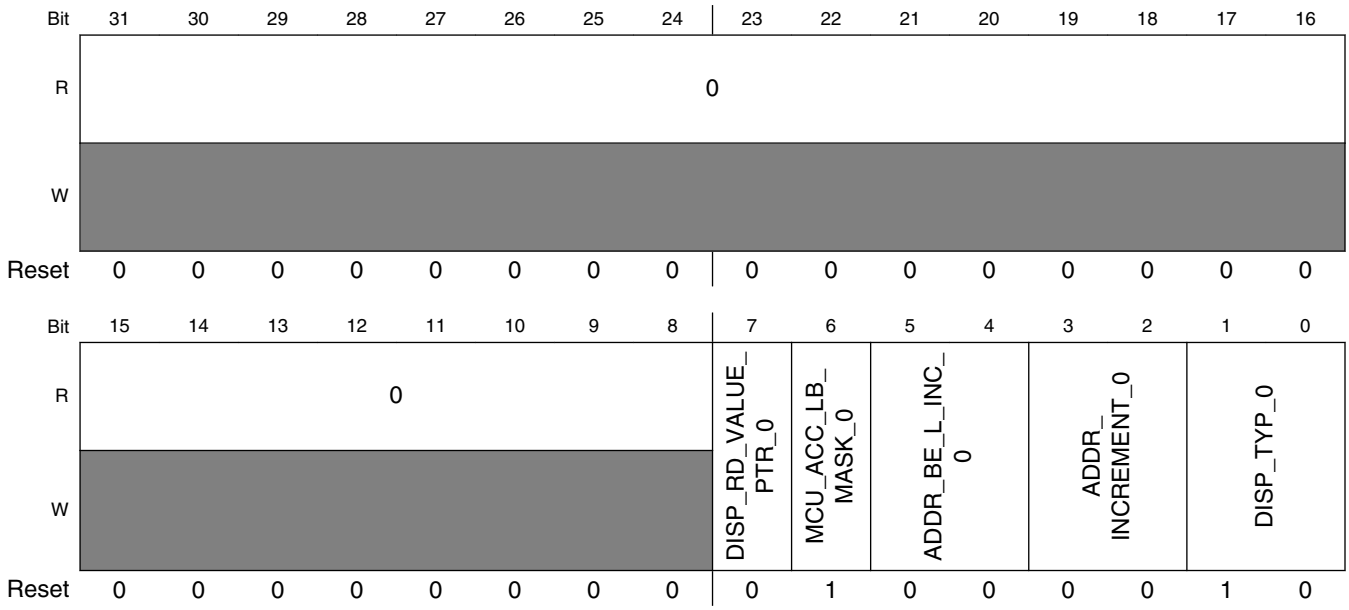
Table continues on the next page...

IPUx_DC_GEN field descriptions (continued)

Field	Description
	1 Enable the asynchronous interface via channel 5 0 normal mode, synchronous flow via channel 5
7 SYNC_ PRIORITY_1	When 2 sync flows are running, this bit sets the priority of channel #1. both SYNC_PRIORITY_5 and SYNC_PRIORITY_1 should not have the value of 0 This bit should be 1 high Priority 0 low Priority
6 SYNC_ PRIORITY_5	When 2 sync flows are running, this bit sets the priority of channel #5. both SYNC_PRIORITY_5 and SYNC_PRIORITY_1 should not have the value of 0 This bit should be 1 high priority 0 low Priority
5 MASK4CHAN_5	Sync flow can be associated with a mask channel. Only one sync flow can have a mask. This bit is ignored if MASK_EN is clear 1 mask channel is associated to the sync flow via DP 0 mask channel is associated to the sync flow via DC (without DP)
4 MASK_EN	Enable of the mask channel 1 mask channel is enabled 0 mask channel is disabled
3 Reserved	This read-only field is reserved and always has the value 0.
2–1 SYNC_1_6	This field 00 Channel 1 of the DC handles async flow 01 Illegal 10 Channel 1 of the DC handles sync flow 11 illegal
0 Reserved	This read-only field is reserved and always has the value 0.

37.5.322 DC Display Configuration 1 Register 0 (IPUx_DC_DISP_CONF1_0)

Address: Base address + 5_80D8h offset



IPUx_DC_DISP_CONF1_0 field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 DISP_RD_VALUE_PTR_0	When the display works in wait for status mode. The IPU polls the display and compare the value to the value stored on the status DI_READ_DATA_ACK_VALUE and mask it with DI_READ_DATA_MASK. The DC holds 2 sets of mask and value. This field holds a pointer to the corresponding set of mask and value. 1 DI_READ_DATA_ACK_VALUE_1 & DI_READ_DATA_MASK_1 are used for display 0 0 DI_READ_DATA_ACK_VALUE_0 & DI_READ_DATA_MASK_0 are used for display 0
6 MCU_ACC_LB_MASK_0	The DC compares between the current access to the a calculated address. The calculated address is the next consecutive address following the last address. This bit defines the comparing mode 1 The 2 addresses are fully compared 0 The 2 addresses are compared, but the ADDR[0] bit of the new address is ignored
5–4 ADDR_BE_L_INC_0	This bits define the increment mode when the latest access was done with some of the byte enable signals are low, in that case different increment should be done instead of the normal auto increment of the address IF MCU_ACC_LB_MASK_0 is 0 then only 00 and 10 values are allowed. 00 No increment 01 Increment by 1 10 Increment by 2 11 Increment by 3

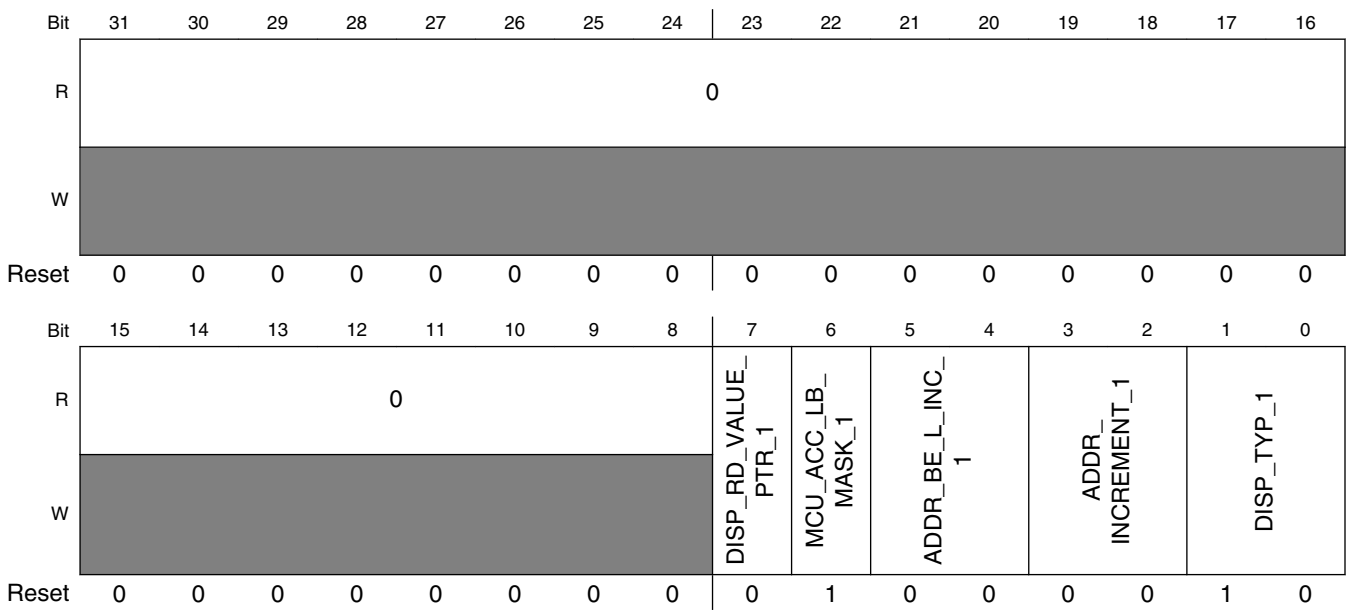
Table continues on the next page...

IPUx_DC_DISP_CONF1_0 field descriptions (continued)

Field	Description
3–2 ADDR_ INCREMENT_0	This field is the increment step for auto increment mode 00 Increment the address by 1 01 Increment the address by 2 10 Increment the address by 3 11 Increment the address by 4
DISP_TYP_0	This field defines the type of the display 00 Serial accesses display 01 Reserved 10 parallel display, without byte_enable support 11 parallel display, with byte_enable support

37.5.323 DC Display Configuration 1 Register 1 (IPUx_DC_DISP_CONF1_1)

Address: Base address + 5_80DCh offset



IPUx_DC_DISP_CONF1_1 field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 DISP_RD_ VALUE_PTR_1	When the display works in wait for status mode. The IPU polls the display and compare the value to the value stored on the status DI_READ_DATA_ACK_VALUE and mask it with DI_READ_DATA_MASK. The DC holds 2 sets of mask and value. This field holds a pointer to the corresponding set of mask and value.

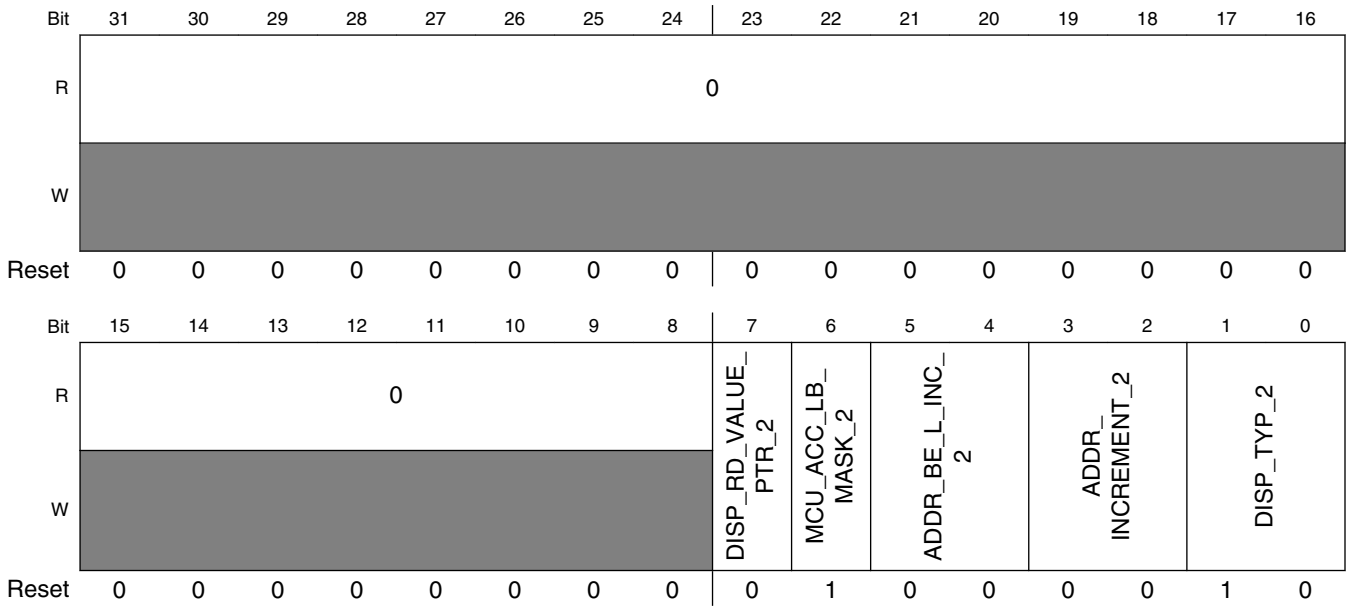
Table continues on the next page...

IPUx_DC_DISP_CONF1_1 field descriptions (continued)

Field	Description
	1 DI_READ_DATA_ACK_VALUE_1 & DI_READ_DATA_MASK_1 are used for display 1 0 DI_READ_DATA_ACK_VALUE_0 & DI_READ_DATA_MASK_0 are used for display 1
6 MCU_ACC_LB_MASK_1	The DC compares between the current access to the a calculated address. The calculated address is the next consecutive address following the last address. This bit defines the comparing mode 1 The 2 addresses are fully compared 0 The 2 addresses are compared, but the ADDR[0] bit of the new address is ignored
5–4 ADDR_BE_L_INC_1	This bits define the increment mode when the latest access was done with some of the byte enable signals are low, in that case different increment should be done instead of the normal auto increment of the address IF MCU_ACC_LB_MASK_1 is 0 then only 00 and 10 values are allowed. 00 No increment 01 Increment by 1 10 Increment by 2 11 Increment by 3
3–2 ADDR_INCREMENT_1	This field is the increment step for auto increment mode 00 Increment the address by 1 01 Increment the address by 2 10 Increment the address by 3 11 Increment the address by 4
DISP_TYP_1	This field defines the type of the display 00 Serial accesses display 01 Reserved 10 parallel display, without byte_enable support 11 parallel display, with byte_enable support

37.5.324 DC Display Configuration 1 Register 2 (IPUx_DC_DISP_CONF1_2)

Address: Base address + 5_80E0h offset



IPUx_DC_DISP_CONF1_2 field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 DISP_RD_VALUE_PTR_2	When the display works in wait for status mode. The IPU polls the display and compare the value to the value stored on the status DI_READ_DATA_ACK_VALUE and mask it with DI_READ_DATA_MASK. The DC holds 2 sets of mask and value. This field holds a pointer to the corresponding set of mask and value. 1 DI_READ_DATA_ACK_VALUE_1 & DI_READ_DATA_MASK_1 are used for display 2 0 DI_READ_DATA_ACK_VALUE_0 & DI_READ_DATA_MASK_0 are used for display 2
6 MCU_ACC_LB_MASK_2	The DC compares between the current access to the a calculated address. The calculated address is the next consecutive address following the last address. This bit defines the comparing mode 1 The 2 addresses are fully compared 0 The 2 addresses are compared, but the ADDR[0] bit of the new address is ignored
5–4 ADDR_BE_L_INC_2	This bits define the increment mode when the latest access was done with some of the byte enable signals are low, in that case different increment should be done instead of the normal auto increment of the address IF MCU_ACC_LB_MASK_2 is 0 then only 00 and 10 values are allowed. 00 No increment 01 Increment by 1 10 Increment by 2 11 Increment by 3

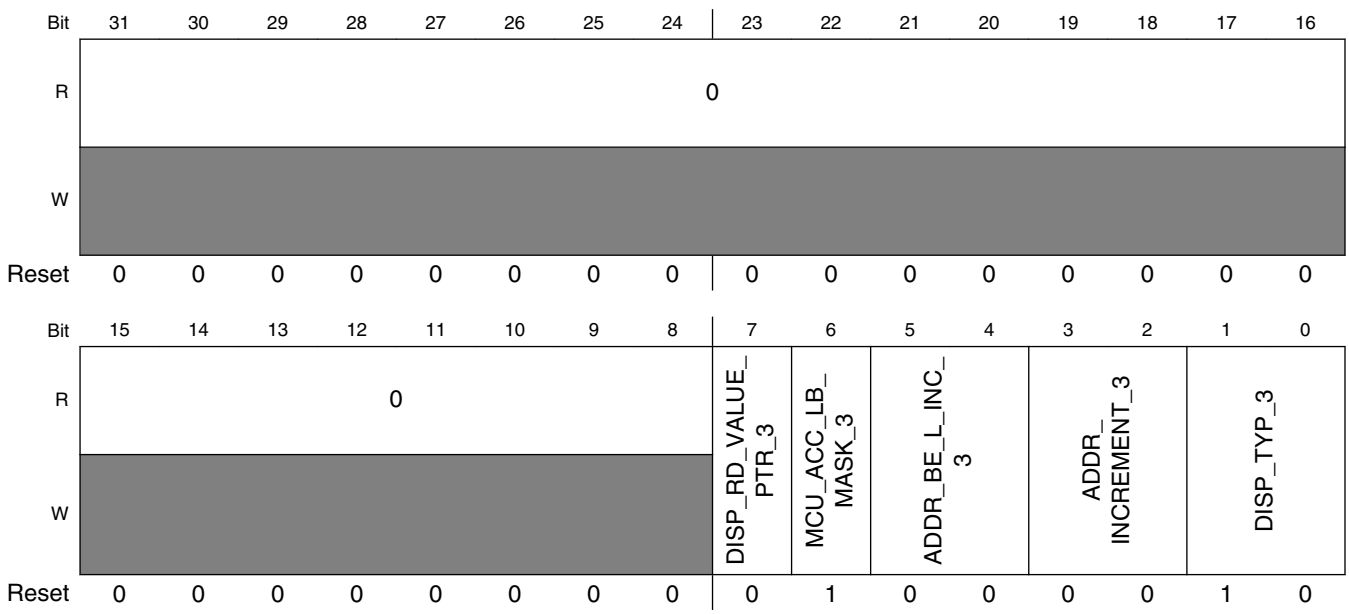
Table continues on the next page...

IPUx_DC_DISP_CONF1_2 field descriptions (continued)

Field	Description
3–2 ADDR_ INCREMENT_2	This field is the increment step for auto increment mode 00 Increment the address by 1 01 Increment the address by 2 10 Increment the address by 3 11 Increment the address by 4
DISP_TYP_2	This field defines the type of the display 00 Serial accesses display 01 Reserved 10 parallel display, without byte_enable support 11 parallel display, with byte_enable support

37.5.325 DC Display Configuration 1 Register 3 (IPUx_DC_DISP_CONF1_3)

Address: Base address + 5_80E4h offset



IPUx_DC_DISP_CONF1_3 field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 DISP_RD_ VALUE_PTR_3	When the display works in wait for status mode. The IPU polls the display and compare the value to the value stored on the status DI_READ_DATA_ACK_VALUE and mask it with DI_READ_DATA_MASK. The DC holds 2 sets of mask and value. This field holds a pointer to the corresponding set of mask and value.

Table continues on the next page...

IPUx_DC_DISP_CONF1_3 field descriptions (continued)

Field	Description
	1 DI_READ_DATA_ACK_VALUE_1 & DI_READ_DATA_MASK_1 are used for display 3 0 DI_READ_DATA_ACK_VALUE_0 & DI_READ_DATA_MASK_0 are used for display 3
6 MCU_ACC_LB_MASK_3	The DC compares between the current access to the a calculated address. The calculated address is the next consecutive address following the last address. This bit defines the comparing mode 1 The 2 addresses are fully compared 0 The 2 addresses are compared, but the ADDR[0] bit of the new address is ignored
5–4 ADDR_BE_L_INC_3	This bits define the increment mode when the latest access was done with some of the byte enable signals are low, in that case different increment should be done instead of the normal auto increment of the address IF MCU_ACC_LB_MASK_3 is 0 then only 00 and 10 values are allowed. 00 No increment 01 Increment by 1 10 Increment by 2 11 Increment by 3
3–2 ADDR_INCREMENT_3	This field is the increment step for auto increment mode 00 Increment the address by 1 01 Increment the address by 2 10 Increment the address by 3 11 Increment the address by 4
DISP_TYP_3	This field defines the type of the display 00 Serial accesses display 01 Reserved 10 parallel display, without byte_enable support 11 parallel display, with byte_enable support

37.5.326 DC Display Configuration 2 Register 0 (IPUx_DC_DISP_CONF2_0)

IPUx_DMFC_RD_CHAN field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value 0.
25–24 dmfc_ppw_c	Pixel Per Word coded. This field defines the size of the read data from the display. 00 8 bit per pixel 01 16 bit per pixel 10 24 (rgb) bit per pixel or 32 bit per pixel 11 Reserved
23–21 dmfc_wm_clr_0	Watermark Clear This field defines the watermark's level of the DMFC read FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of free bursts at the FIFO (dmfc_wm_clr_0 > dmfc_wm_set_0)
20–18 dmfc_wm_set_0	Watermark Set This field defines the watermark's level of the DMFC read FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of free bursts at the FIFO (dmfc_wm_clr_0 > dmfc_wm_set_0)
17 dmfc_wm_en_0	Watermark enable. This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
16–8 Reserved	This read-only field is reserved and always has the value 0.
7–6 dmfc_burst_size_0	Read burst Size This field defines the burst size of the DMFC's read accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 32 words of 128 bit (4 pixels of 32 bit each, going to the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
Reserved	This read-only field is reserved and always has the value 0.

37.5.384 DMFC Write Channel Register (IPUx_DMFC_WR_CHAN)

Address: Base address + 6_0004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0 Reserved	This read-only field is reserved and always has the value 0.

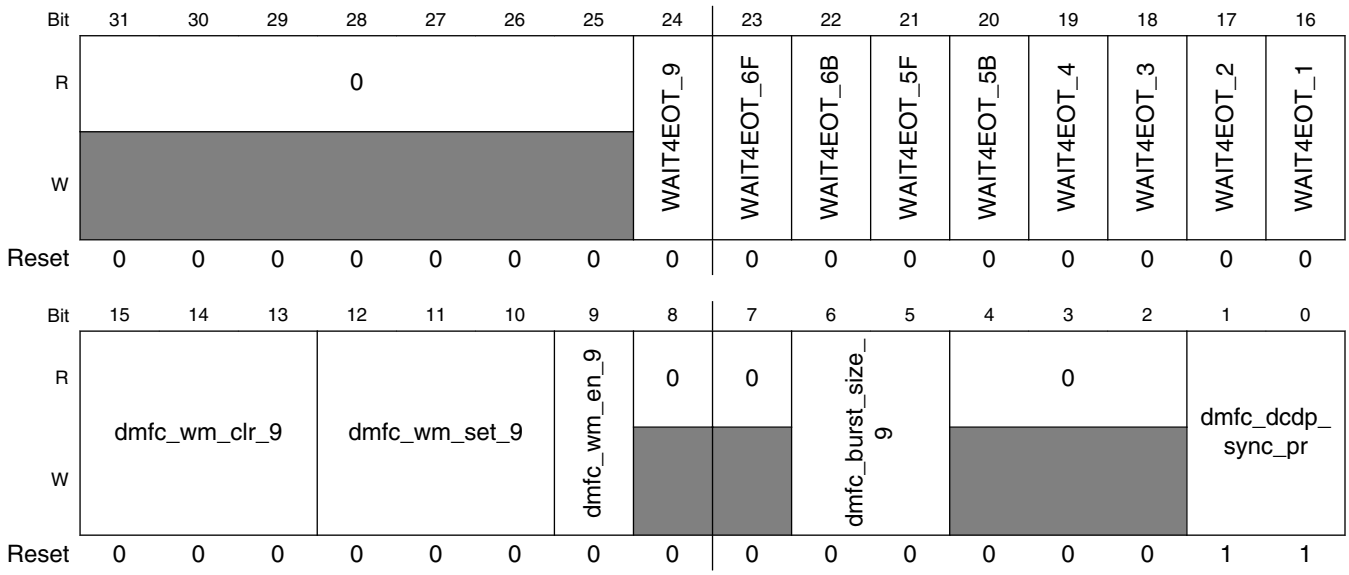
37.5.388 DMFC General 1 Register (IPUx_DMFC_GENERAL_1)

Address: Base address + 6_0014h offset



IPUx_DMFC_GENERAL_1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 WAIT4EOT_9	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #9 is in wait4eot mode 0 FIFO #9 is in normal mode
23 WAIT4EOT_6F	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6F is in wait4eot mode 0 FIFO #6F is in normal mode
22 WAIT4EOT_6B	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6B is in wait4eot mode 0 FIFO #6B is in normal mode

Table continues on the next page...

IPUx_DMFC_GENERAL_1 field descriptions (continued)

Field	Description
21 WAIT4EOT_5F	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #5F is in wait4eot mode 0 FIFO #5F is in normal mode
20 WAIT4EOT_5B	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #5B is in wait4eot mode 0 FIFO #5B is in normal mode
19 WAIT4EOT_4	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #4 is in wait4eot mode 0 FIFO #4 is in normal mode
18 WAIT4EOT_3	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #3 is in wait4eot mode 0 FIFO #3 is in normal mode
17 WAIT4EOT_2	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #2 is in wait4eot mode 0 FIFO #2 is in normal mode
16 WAIT4EOT_1	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #1 is in wait4eot mode 0 FIFO #1 is in normal mode
15–13 dmfc_wm_clr_9	Watermark Clear This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)

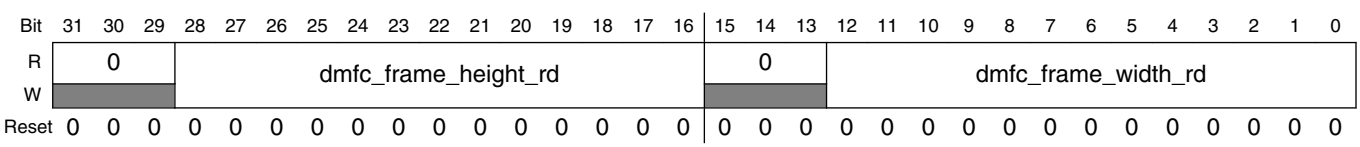
Table continues on the next page...

IPUx_DMFC_GENERAL_1 field descriptions (continued)

Field	Description
12–10 dmfc_wm_set_9	Watermark Set This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
9 dmfc_wm_en_9	Watermark enable. This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
8 Reserved	This read-only field is reserved and always has the value 0.
7 Reserved	This read-only field is reserved and always has the value 0.
6–5 dmfc_burst_size_9	Burst size of IDMAC's channel 44 This field defines the burst size of the IDMAC's channel 44 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. This channel is targeted for MASK - the FIFO size is always 32X128; The base address is always the upper half of the 8th segment 00 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
4–2 Reserved	This read-only field is reserved and always has the value 0.
dmfc_dcdp_sync_pr	DMFC's memory access priority settings for simultaneous synchronous flows from DC & DP 00 Forbidden - should not be used. 01 DC has higher priority over DP 10 DP has higher priority over DC 11 Round Robin

37.5.389 DMFC General 2 Register (IPUx_DMFC_GENERAL_2)

Address: Base address + 6_0018h offset



IPUx_DMFC_GENERAL_2 field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28–16 dmfc_frame_ height_rd	Frame height for read channel from the display to the IDMAC; Units are pixels
15–13 Reserved	This read-only field is reserved and always has the value 0.
dmfc_frame_ width_rd	Frame width for read channel from the display to the IDMAC; Units are pixels

37.5.390 DMFC IC Interface Control Register (IPUx_DMFC_IC_CTRL)

Address: Base address + 6_001Ch offset

IPUx_DMFC_WR_CHAN_ALT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–14 dmfc_burst_size_2_alt	Burst size of IDMAC's channel 41 (for alternate flow) This field defines the burst size of the IDMAC's channel 41 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
13–11 dmfc_fifo_size_2_alt	DMFC FIFO size for IDMAC's channel 41 (for alternate flow) This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 41 000 All (512X128 words) the DMFC's FIFO is allocated to this channel 001 256X128 words are allocated to this channel 010 128X128 words are allocated to this channel

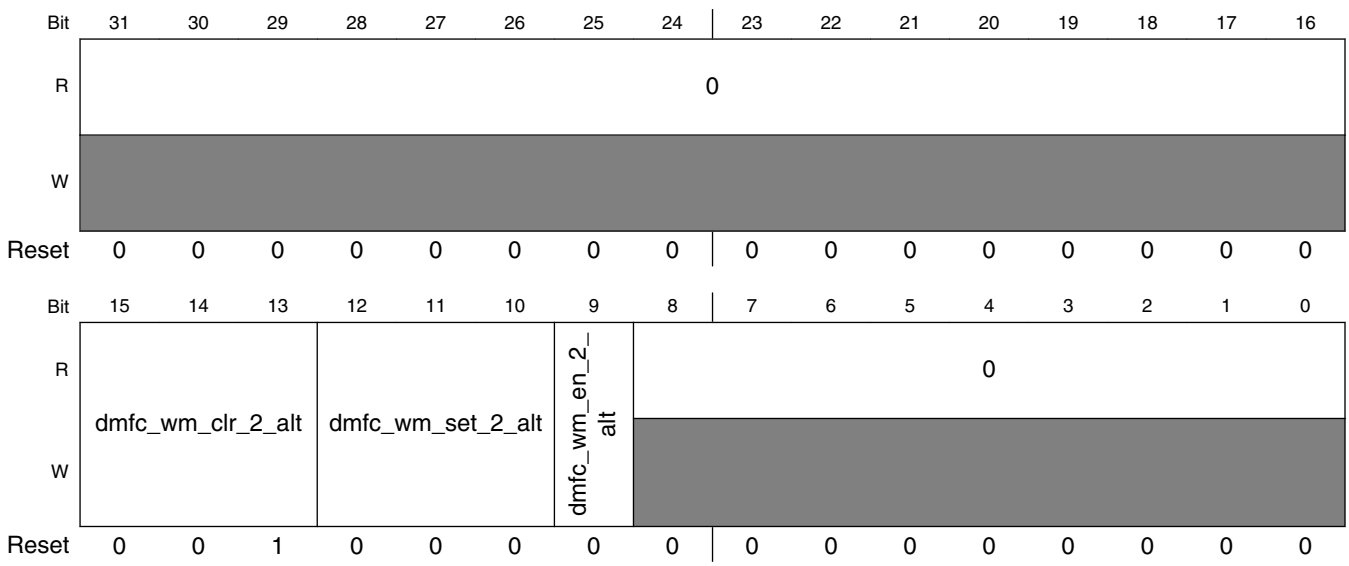
Table continues on the next page...

IPUx_DMFC_WR_CHAN_ALT field descriptions (continued)

Field	Description
	011 64X128 words are allocated to this channel 100 32X128 words are allocated to this channel 101 16X128 words are allocated to this channel 110 8X128 words are allocated to this channel 111 4X128 words are allocated to this channel
10–8 dmfc_st_addr_2_alt	DMFC Start Address for IDMAC's channel 41 (for alternate flow) This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 41. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 Segment 0 001 Segment 1 111 Segment 7
Reserved	This read-only field is reserved and always has the value 0.

37.5.392 DMFC Write Channel Definition Alternate Register (IPUx_DMFC_WR_CHAN_DEF_ALT)

Address: Base address + 6_0024h offset



IPUx_DMFC_WR_CHAN_DEF_ALT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.

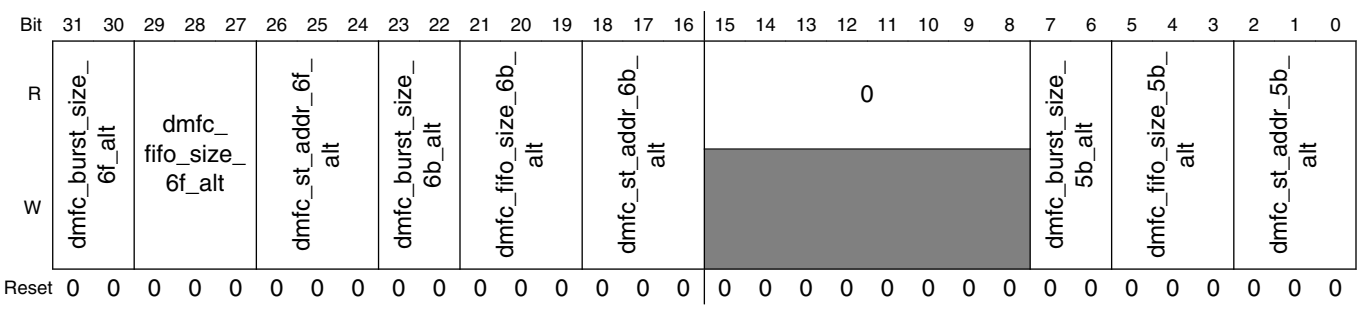
Table continues on the next page...

IPUx_DMFC_WR_CHAN_DEF_ALT field descriptions (continued)

Field	Description
15–13 dmfc_wm_clr_2_alt	Watermark Clear (for alternate flow) This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)
12–10 dmfc_wm_set_2_alt	Watermark Set (for alternate flow) This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
9 dmfc_wm_en_2_alt	Watermark enable. (for alternate flow) This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
Reserved	This read-only field is reserved and always has the value 0.

37.5.393 DMFC MFC Display Processor Channel Alternate Register (IPUx_DMFC_DP_CHAN_ALT)

Address: Base address + 6_0028h offset



IPUx_DMFC_DP_CHAN_ALT field descriptions

Field	Description
31–30 dmfc_burst_size_6f_alt	Burst size of IDMAC's channel 29 (for alternate flow) This field defines the burst size of the IDMAC's channel 29 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
29–27 dmfc_fifo_size_6f_alt	DMFC FIFO size for IDMAC's channel 29 (for alternate flow) This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 29 000 All (512X128 words) the DMFC's FIFO is allocated to this channel

Table continues on the next page...

IPUx_DMFC_DP_CHAN_ALT field descriptions (continued)

Field	Description
	001 256X128 words are allocated to this channel 010 128X128 words are allocated to this channel 011 64X128 words are allocated to this channel 100 32X128 words are allocated to this channel 101 16X128 words are allocated to this channel 110 8X128 words are allocated to this channel 111 4X128 words are allocated to this channel
26–24 dmfc_st_addr_6f_alt	DMFC Start Address for IDMAC's channel 29 (for alternate flow) This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 29. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 Segment 0 001 Segment 1 111 Segment 7
23–22 dmfc_burst_size_6b_alt	Burst size of IDMAC's channel 24 (for alternate flow) This field defines the burst size of the IDMAC's channel 24 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
21–19 dmfc_fifo_size_6b_alt	DMFC FIFO size for IDMAC's channel 24 (for alternate flow) This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 24 000 All (512X128 words) the DMFC's FIFO is allocated to this channel 001 256X128 words are allocated to this channel 010 128X128 words are allocated to this channel 011 64X128 words are allocated to this channel 100 32X128 words are allocated to this channel 101 16X128 words are allocated to this channel 110 8X128 words are allocated to this channel 111 4X128 words are allocated to this channel
18–16 dmfc_st_addr_6b_alt	DMFC Start Address for IDMAC's channel 24 (for alternate flow) This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 24. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 Segment 0 001 Segment 1 111 Segment 7
15–8 Reserved	This read-only field is reserved and always has the value 0.

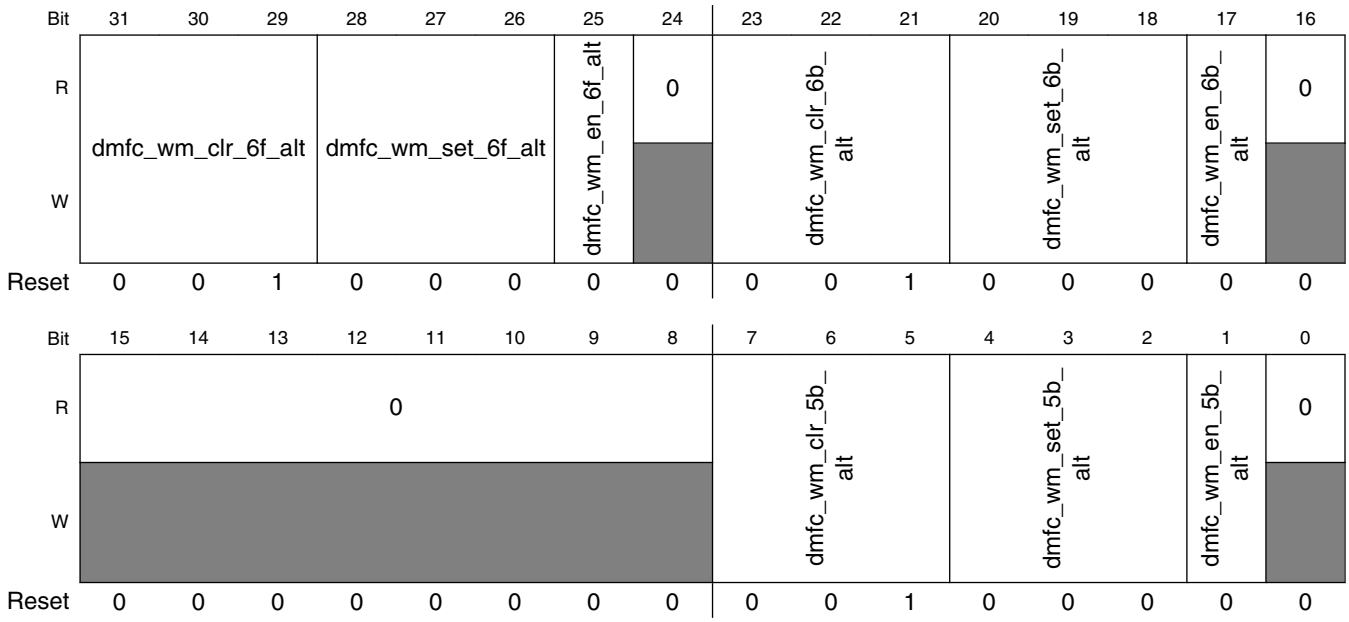
Table continues on the next page...

IPUx_DMFC_DP_CHAN_ALT field descriptions (continued)

Field	Description
7–6 dmfc_burst_size_5b_alt	Burst size of IDMAC's channel 23 (for alternate flow) This field defines the burst size of the IDMAC's channel 23 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
5–3 dmfc_fifo_size_5b_alt	DMFC FIFO size for IDMAC's channel 23 (for alternate flow) This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 23 000 All (512X128 words) the DMFC's FIFO is allocated to this channel 001 256X128 words are allocated to this channel 010 128X128 words are allocated to this channel 011 64X128 words are allocated to this channel 100 32X128 words are allocated to this channel 101 16X128 words are allocated to this channel 110 8X128 words are allocated to this channel 111 4X128 words are allocated to this channel
dmfc_st_addr_5b_alt	DMFC Start Address for IDMAC's channel 23 (for alternate flow) This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 23. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 Segment 0 001 Segment 1 111 Segment 7

37.5.394 DMFC Display Channel Definition Alternate Register (IPUx_DMFC_DP_CHAN_DEF_ALT)

Address: Base address + 6_002Ch offset



IPUx_DMFC_DP_CHAN_DEF_ALT field descriptions

Field	Description
31–29 dmfc_wm_clr_6f_alt	Watermark Clear (for alternate flow) This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)
28–26 dmfc_wm_set_6f_alt	Watermark Set (for alternate flow) This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
25 dmfc_wm_en_6f_alt	Watermark enable. (for alternate flow) This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
24 Reserved	This read-only field is reserved and always has the value 0.
23–21 dmfc_wm_clr_6b_alt	Watermark Clear (for alternate flow) This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)

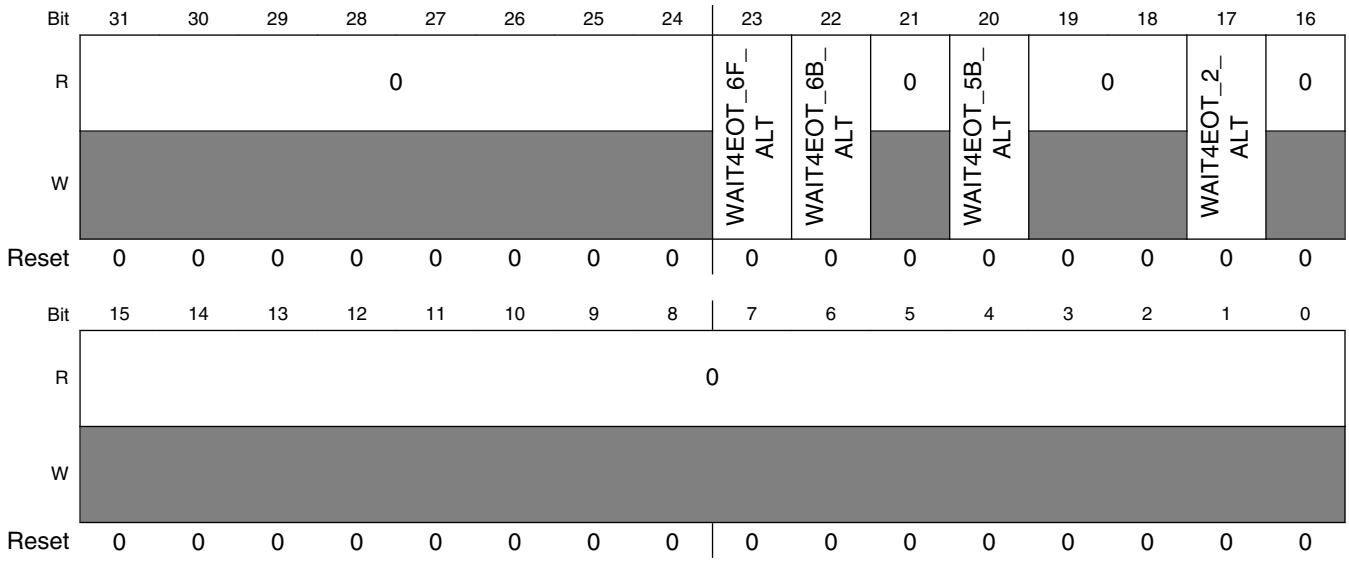
Table continues on the next page...

IPUx_DMFC_DP_CHAN_DEF_ALT field descriptions (continued)

Field	Description
20–18 dmfc_wm_set_ 6b_alt	Watermark Set (for alternate flow) This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
17 dmfc_wm_en_ 6b_alt	Watermark enable. (for alternate flow) This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
16–8 Reserved	This read-only field is reserved and always has the value 0.
7–5 dmfc_wm_clr_ 5b_alt	Watermark Clear (for alternate flow) This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)
4–2 dmfc_wm_set_ 5b_alt	Watermark Set (for alternate flow) This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
1 dmfc_wm_en_ 5b_alt	Watermark enable. (for alternate flow) This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
0 Reserved	This read-only field is reserved and always has the value 0.

37.5.395 DMFC General 1 Alternate Register (IPUx_DMFC_GENERAL1_ALT)

Address: Base address + 6_0030h offset



IPUx_DMFC_GENERAL1_ALT field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 WAIT4EOT_6F_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6F is in wait4eot mode (for alternate flow) 0 FIFO #6F is in normal mode (for alternate flow)
22 WAIT4EOT_6B_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6B is in wait4eot mode (for alternate flow) 0 FIFO #6B is in normal mode (for alternate flow)
21 Reserved	This read-only field is reserved and always has the value 0.
20 WAIT4EOT_5B_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode.

Table continues on the next page...

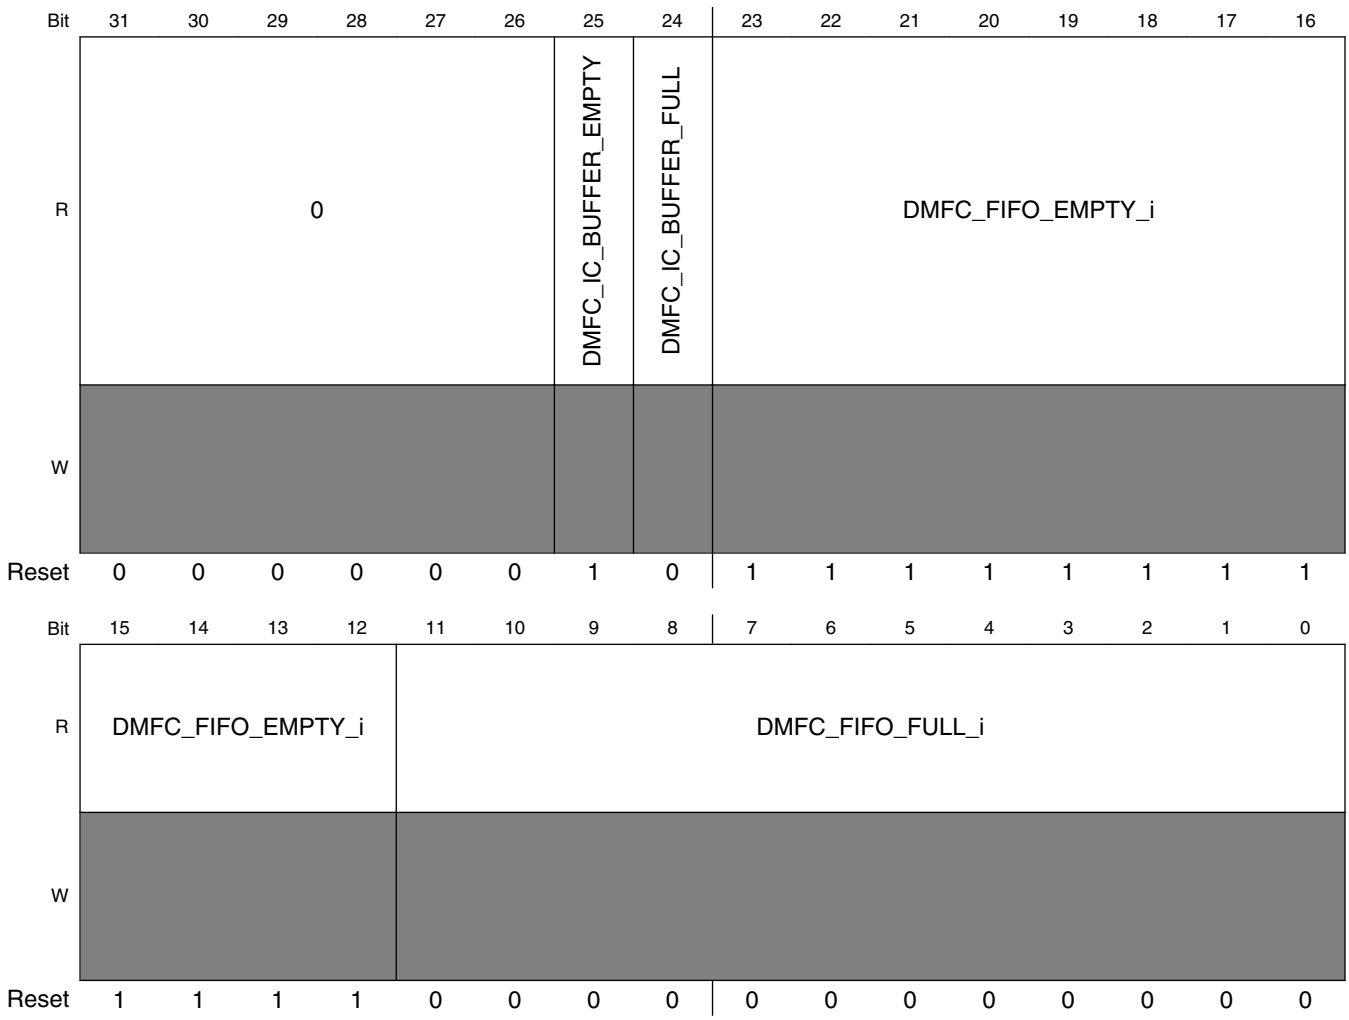
IPUx_DMFC_GENERAL1_ALT field descriptions (continued)

Field	Description
	1 FIFO #5B is in wait4eot mode (for alternate flow) 0 FIFO #5B is in normal mode (for alternate flow)
19–18 Reserved	This read-only field is reserved and always has the value 0.
17 WAIT4EOT_2_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #2 is in wait4eot mode (for alternate flow) 0 FIFO #2 is in normal mode (for alternate flow)
Reserved	This read-only field is reserved and always has the value 0.

37.5.396 DMFC Status Register (IPUx_DMFC_STAT)

This register contains DMFC's status bits. All the bits in this register are read-only.

Address: Base address + 6_0034h offset



IPUx_DMFC_STAT field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value 0.
25 DMFC_IC_ BUFFER_ EMPTY	This bit indicates on a IC FIFO, inside the DMFC, empty condition. 0 IC FIFO not empty 1 IC FIFO is empty

Table continues on the next page...

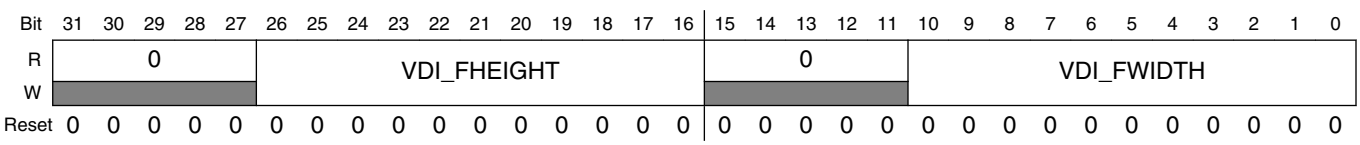
IPUx_DMFC_STAT field descriptions (continued)

Field	Description
24 DMFC_IC_ BUFFER_FULL	This bit indicates on a IC FIFO, inside the DMFC, full condition. 0 IC FIFO not full 1 IC FIFO is full
23–12 DMFC_FIFO_ EMPTY_i	This bit indicates on a DMFC FIFO#<i> empty condition. Mapping of these bit to an actual FIFO number is as follows: bit 0 => 0 bit 1=> 1 bit 2 => 2 bit 3 =>1c bit 4 => 2c bit 5 => 5b bit 6 => 5f bit 7 => 6b bit 8 => 6f bit 9 => 9 bit 10 => 10 (ARM platform access) bit 11 => 11 (ARM platform access) 0 FIFO #<i> is not empty 1 FIFO #<i> is empty
DMFC_FIFO_ FULL_i	This bit indicates on a DMFC FIFO#<i> full condition. Mapping of these bit to an actual FIFO number is as follows: bit 0 => 0 bit 1=> 1 bit 2 => 2 bit 3 =>1c bit 4 => 2c bit 5 => 5b bit 6 => 5f bit 7 => 6b bit 8 => 6f bit 9 => 9 bit 10 => 10 (ARM platform access) bit 11 => 11 (ARM platform access) 0 FIFO #<i> is not full 1 FIFO #<i> is full

37.5.397 VDI Field Size Register (IPUx_VDI_FSIZE)

The register used to control size of VDIC input fields.

Address: Base address + 6_8000h offset



IPUx_VDI_FSIZE field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value 0.
26–16 VDI_FHEIGHT	Frame height The value to be written to this register is the frame's height minus 1. The frame height should not be smaller than 16. When VDI_CMB_EN bit is clear: • The frame height should not be greater than 1080. • The frame's height must be even (which means that both fields have the same height) • The frame's height in 4:2:0 format, must be multiple of 4 (which means that both chroma fields have the same height)

Table continues on the next page...

IPUx_VDI_FSIZE field descriptions (continued)

Field	Description
	When VDI_CMB_EN bit is set: • The frame height should not be greater than 1200.
15–11 Reserved	This read-only field is reserved and always has the value 0.
VDI_FWIDTH	Frame width. The value to be written to this register is the frame's width minus 1. The Frame width should not be smaller than 16. The width must be even. When VDI_CMB_EN bit is clear • The Frame width should not be greater than 720968. When VDI_CMB_EN bit is set: • The Frame width should not be greater than 1920.

37.5.398 VDI Control Register (IPUx_VDI_C)

The register used to control modes of operations of VDIC module.

Address: Base address + 6_8004h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IPUx_VDI_C field descriptions

Field	Description
31 -	VDIC top filed (automatic) This defines what would be the top field to be processed when the data is coming from the CSI 0 top field is field 0 1 top field is field 1
30 -	VDIC top filed (manual) This defines what would be the next top field to be processed when the data is coming from the memory

Table continues on the next page...

IPUx_VDI_C field descriptions (continued)

Field	Description
	0 top field is field 0 1 top field is field 1
29–28 Reserved	This read-only field is reserved and always has the value 0.
27–25 VDI_VWM3_CLR	VDIC WaterMark "clear" level for channel 3. 0 clear watermark level when FIFO3 is full on 1/8 of their size. 1 clear watermark level when FIFO3 is full on 2/8 of their size. 7 clear watermark level when FIFO3 is full.
24–22 VDI_VWM3_SET	VDIC WaterMark "set" level for channel 3. 0 set watermark level when FIFO3 is full on 1/8 of their size. 1 set watermark level when FIFO3 is full on 2/8 of their size. 7 set watermark level when FIFO3 is full.
21–19 VDI_VWM1_CLR	VDIC WaterMark "clear" level for channel 1 or channel 4 (channels 1 and 4 are not working simultaneously). 0 clear watermark level when FIFO1 is full on 1/8 of their size. 1 clear watermark level when FIFO1 is full on 2/8 of their size. 7 clear watermark level when FIFO1 is full.
18–16 VDI_VWM1_SET	VDIC WaterMark "set" level for channel 1 or channel 2 (channels 1 and 4 are not working simultaneously). 0 set watermark level when FIFO1 is full on 1/8 of their size. 1 set watermark level when FIFO1 is full on 2/8 of their size. 7 set watermark level when FIFO1 is full.
15–12 VDI_BURST_ SIZE3	Burst Size for channel 3. The VDIC's burst size is restrict by the IDMAC's restriction - This value must match the IDMAC settings and follow the IDMAC's restrictions 0 Burst size is 1 access. 1 Burst size is 2 accesses. 15 Burst size is 16 accesses.
11–8 VDI_BURST_ SIZE2	Burst Size for channel 2. The VDIC's burst size is restrict by the IDMAC's restriction - This value must match the IDMAC settings and follow the IDMAC's restrictions 0 Burst size is 1 access. 1 Burst size is 2 accesses. 15 Burst size is 16 accesses.
7–4 VDI_BURST_ SIZE1	Burst Size for channels 1 or 4 (channels 1 and 4 are not working simultaneously). The VDIC's burst size is restrict by the IDMAC's restriction - This value must match the IDMAC settings and follow the IDMAC's restrictions 0 Burst size is 1 access. 1 Burst size is 2 accesses. 15 Burst size is 16 accesses.
3–2 VDI_MOT_SEL	Motion select.

Table continues on the next page...

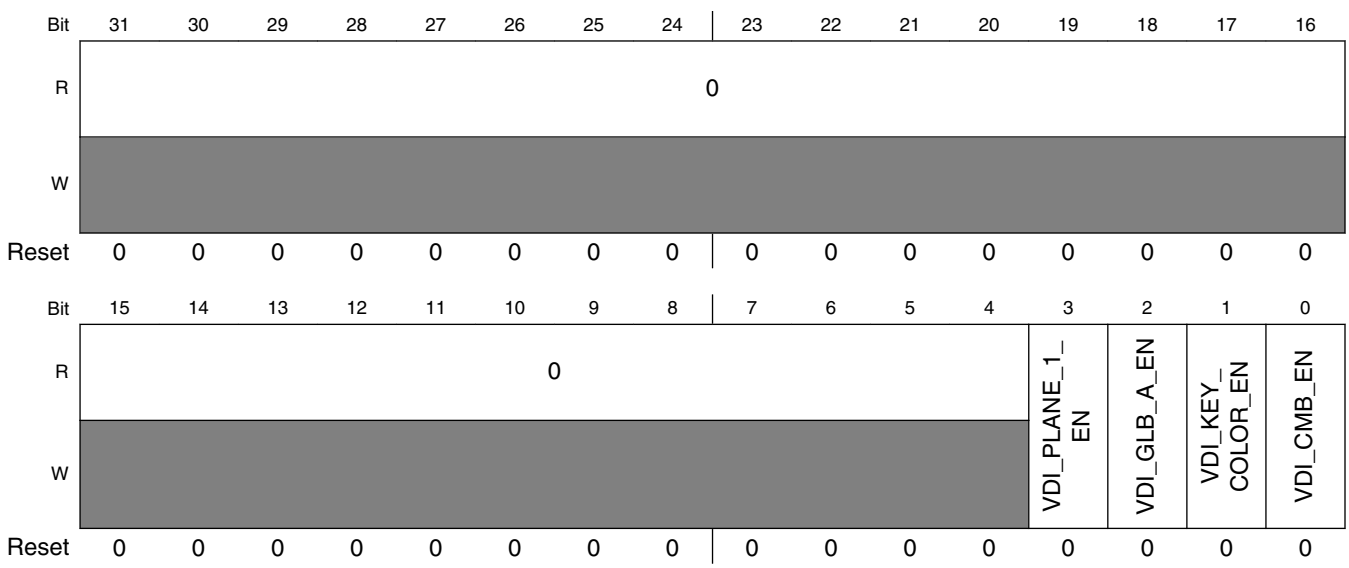
IPUx_VDI_C field descriptions (continued)

Field	Description
	0 Motion determined by ROM "1" (shared toward medium/high motion). 1 Motion determined by ROM "2" (This option will not work well for high motion). 2 Full motion, only vertical filter is used 3 Forbidden.
1 VDI_CH_422	Chroma format at input and output of VDIC. 0 Chroma format is 420. 1 Chroma format is 422.
0 Reserved	This read-only field is reserved and always has the value 0.

37.5.399 VDI Control Register 2 (IPUx_VDI_C2_)

The register used to control modes of operations of VDIC module.

Address: Base address + 6_8008h offset



IPUx_VDI_C2_ field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
3 VDI_PLANE_1_EN	Plane 1 enable 0 plane #1 is disabled 1 plane #1 is enabled

Table continues on the next page...

IPUx_VDI_C2_ field descriptions (continued)

Field	Description
2 VDI_GLB_A_EN	Global alpha enable 0 Alpha is local 1 Alpha is global
1 VDI_KEY_ COLOR_EN	Key Color Enable 0 Key Color disabled. 1 Key color enabled
0 VDI_CMB_EN	Combining enable 0 Combining disabled. The VDIC works in de-interlacing mode 1 Combining enabled. The de-interlacing mode is not functional

37.5.400 VDI Combining Parameters Register 1 (IPUx_VDI_CMDP_1)

The register holds combining paramemters.

Address: Base address + 6_800Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 38
Keypad Port (KPP)

38.1 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O).

The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

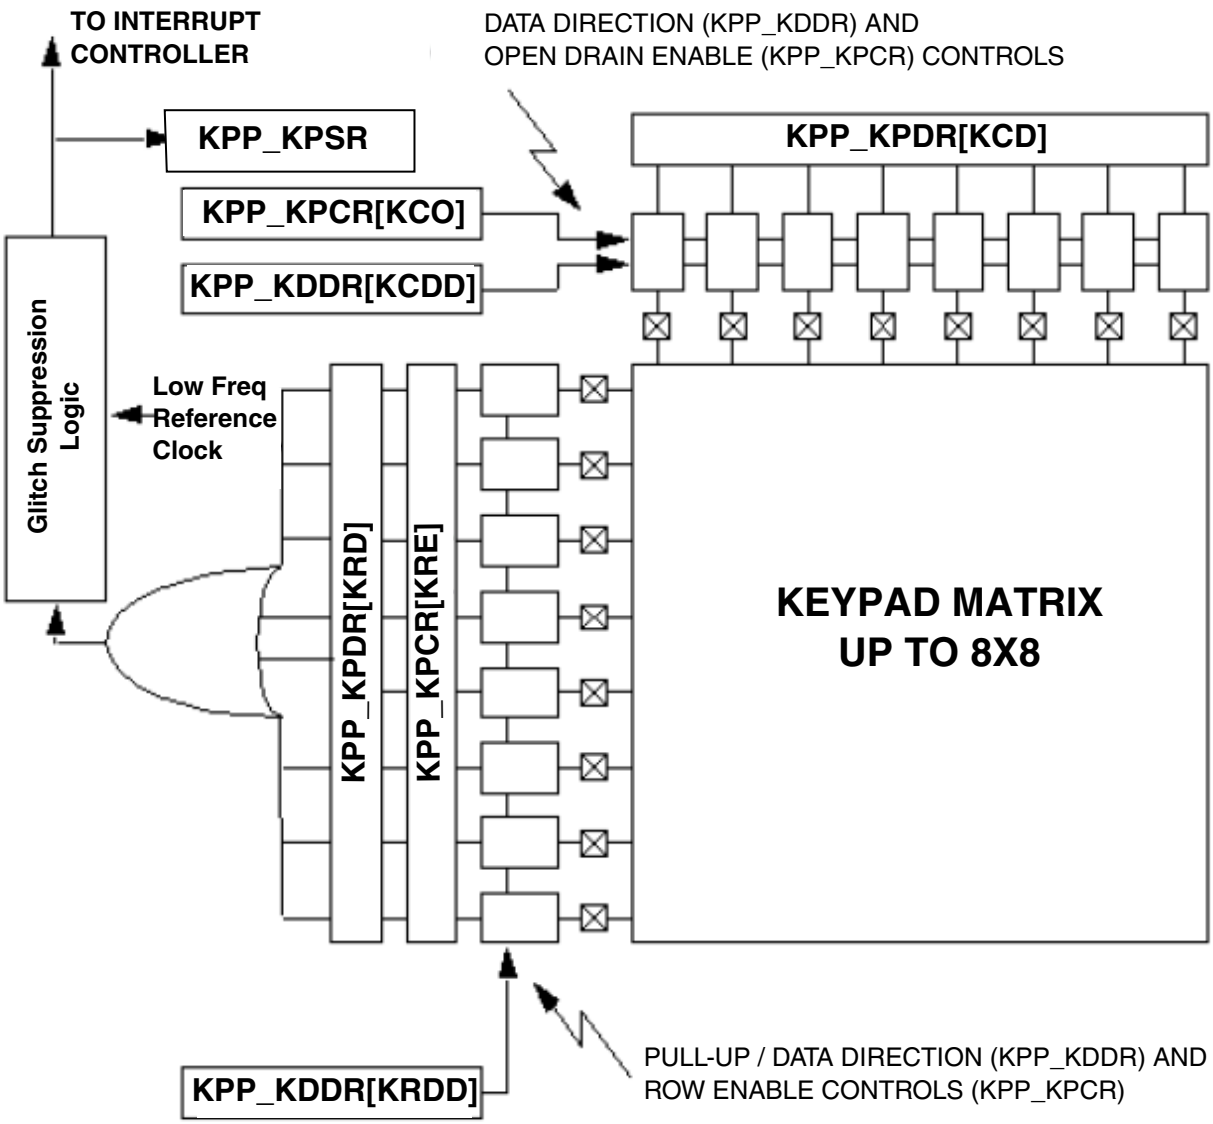

Figure 38-1. KPP Peripheral Block Diagram

38.1.1 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

38.1.2 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

38.2 Clocks

The table found here describes the clock sources for KPP.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 38-1. KPP Clocks

Clock name	Clock Root	Description
ipg_clk_32k	ckil_sync_clk_root	Low-frequency reference clock (32kHz)
ipg_clk_s	ipg_clk_root	Peripheral access clock

38.3 External Signals

There are several pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See the table below for the list of external signals.

Table 38-2. KPP External Signals

Signal	Description	Pad	Mode	Direction
KEY_COL0	Column input or output pin, from chip	KEY_COL0	ALT3	I/O

Table 38-2. KPP External Signals (continued)

Signal	Description	Pad	Mode	Direction
		GPIO_5	ALT2	
		SD2_DAT0	ALT4	

38.3.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

38.3.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

Table 38-3. Keypad Port Column Modes

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole capability should be provided for column pins. Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced.

38.3.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

38.4 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

38.4.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

38.4.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

38.4.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

38.4.4 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the ARM platform if any key is pressed.

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

38.4.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock source.

This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

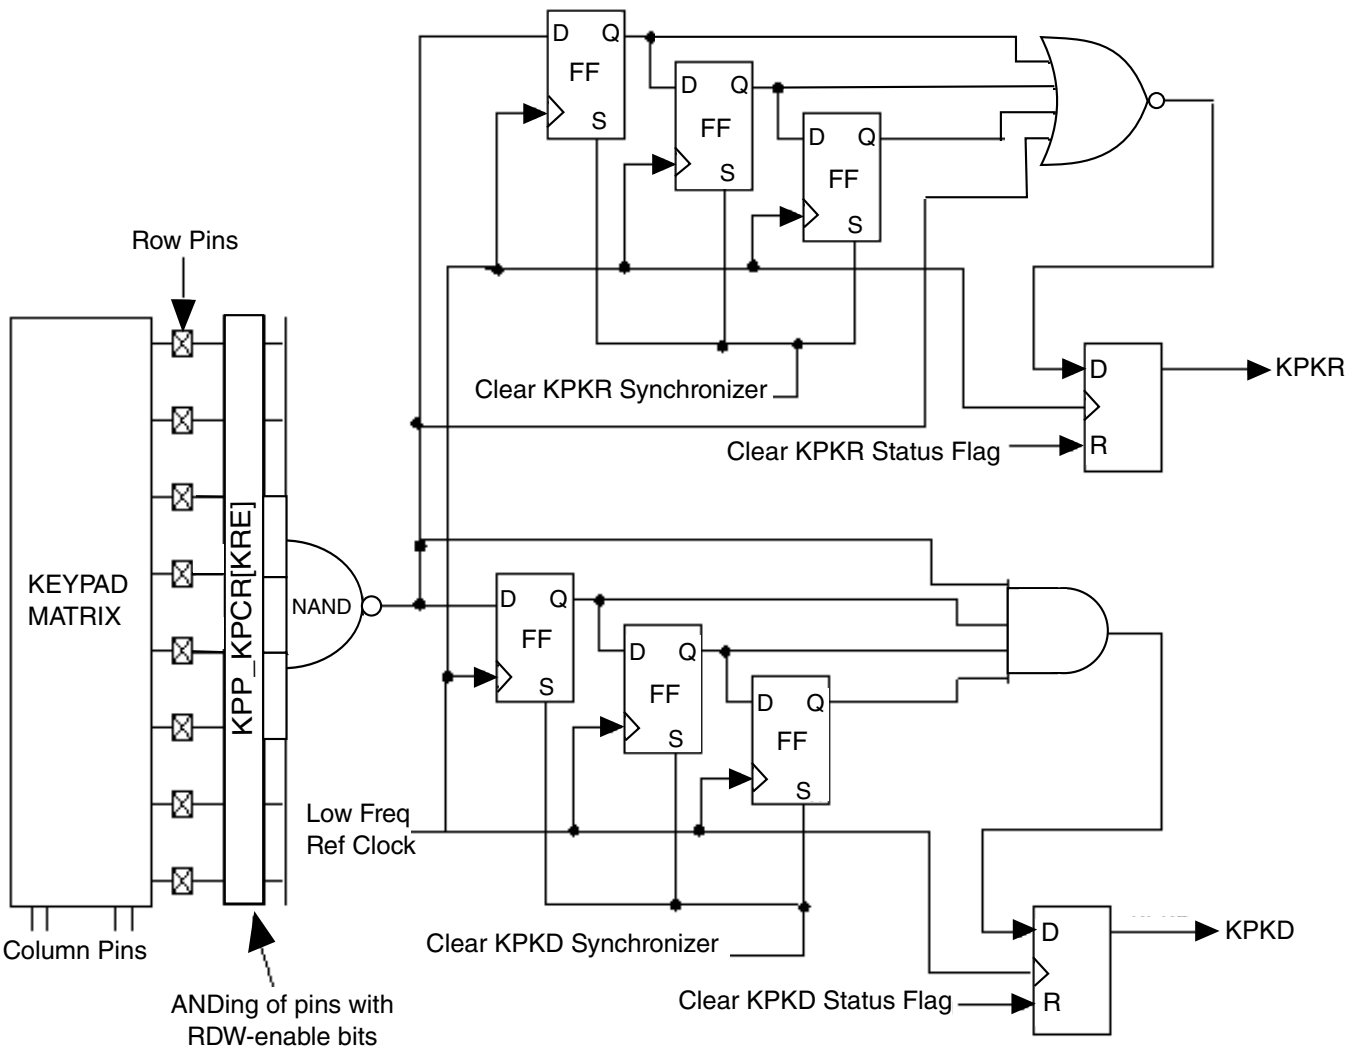

Figure 38-2. Keypad Synchronizer Functional Diagram

38.4.6 Multiple Key Closures

Using the key press and Key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly.

See the following figures for illustrations of the interfacing of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected. Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

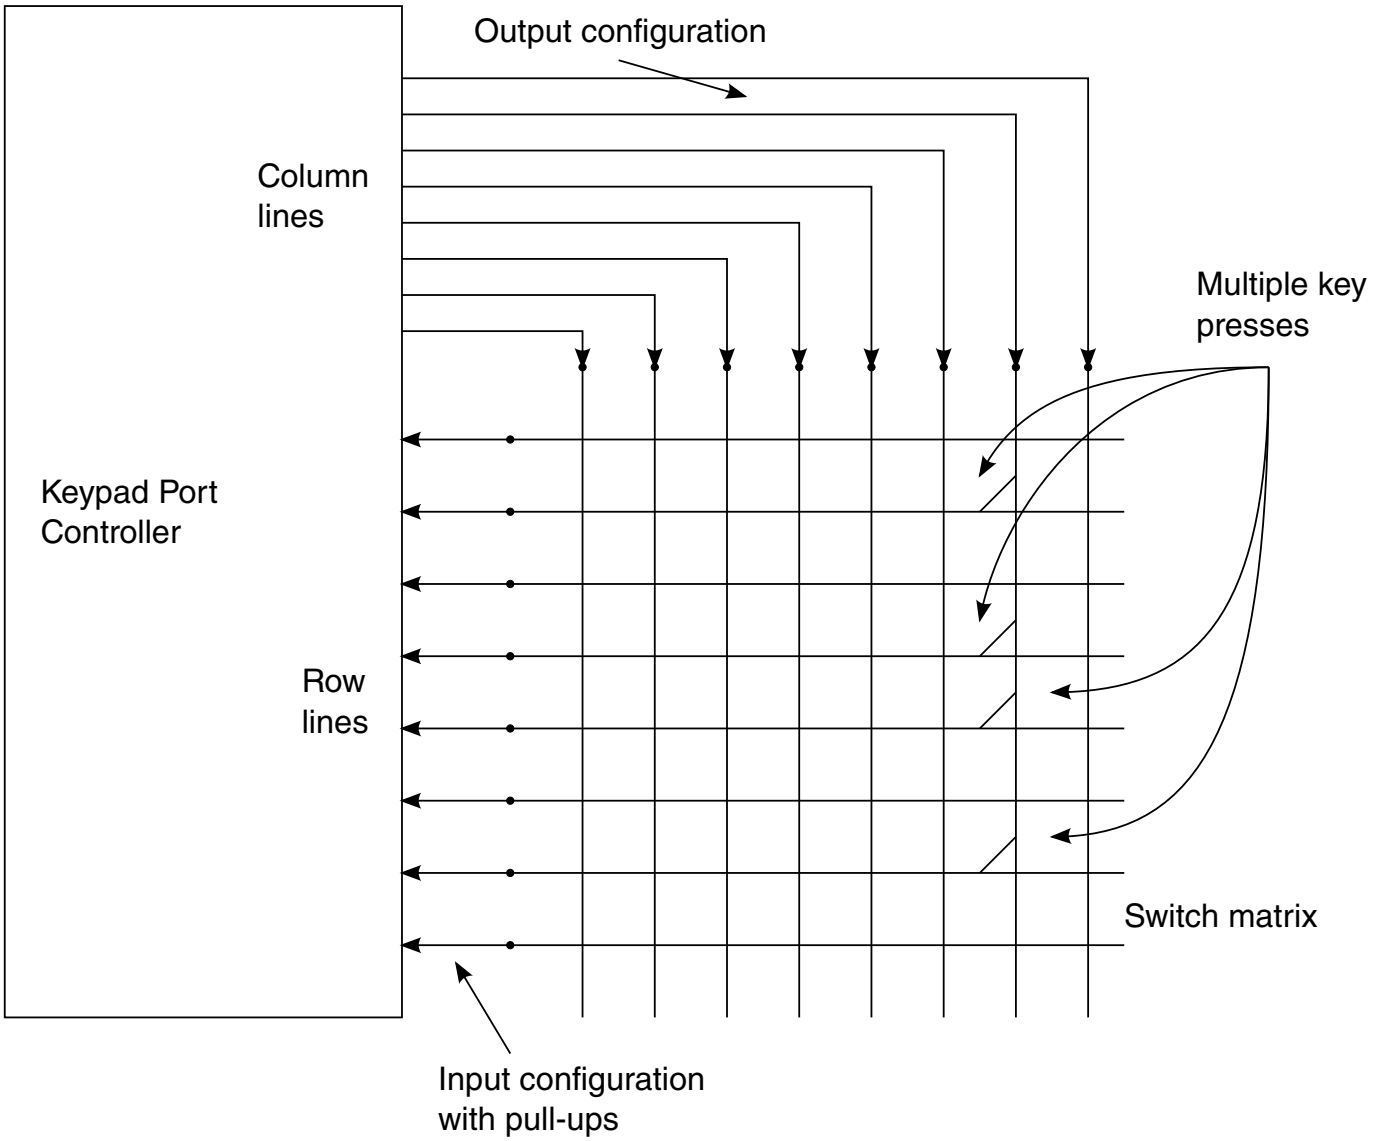

Figure 38-3. Multiple Key Presses on Same Column Line (Simplified View)

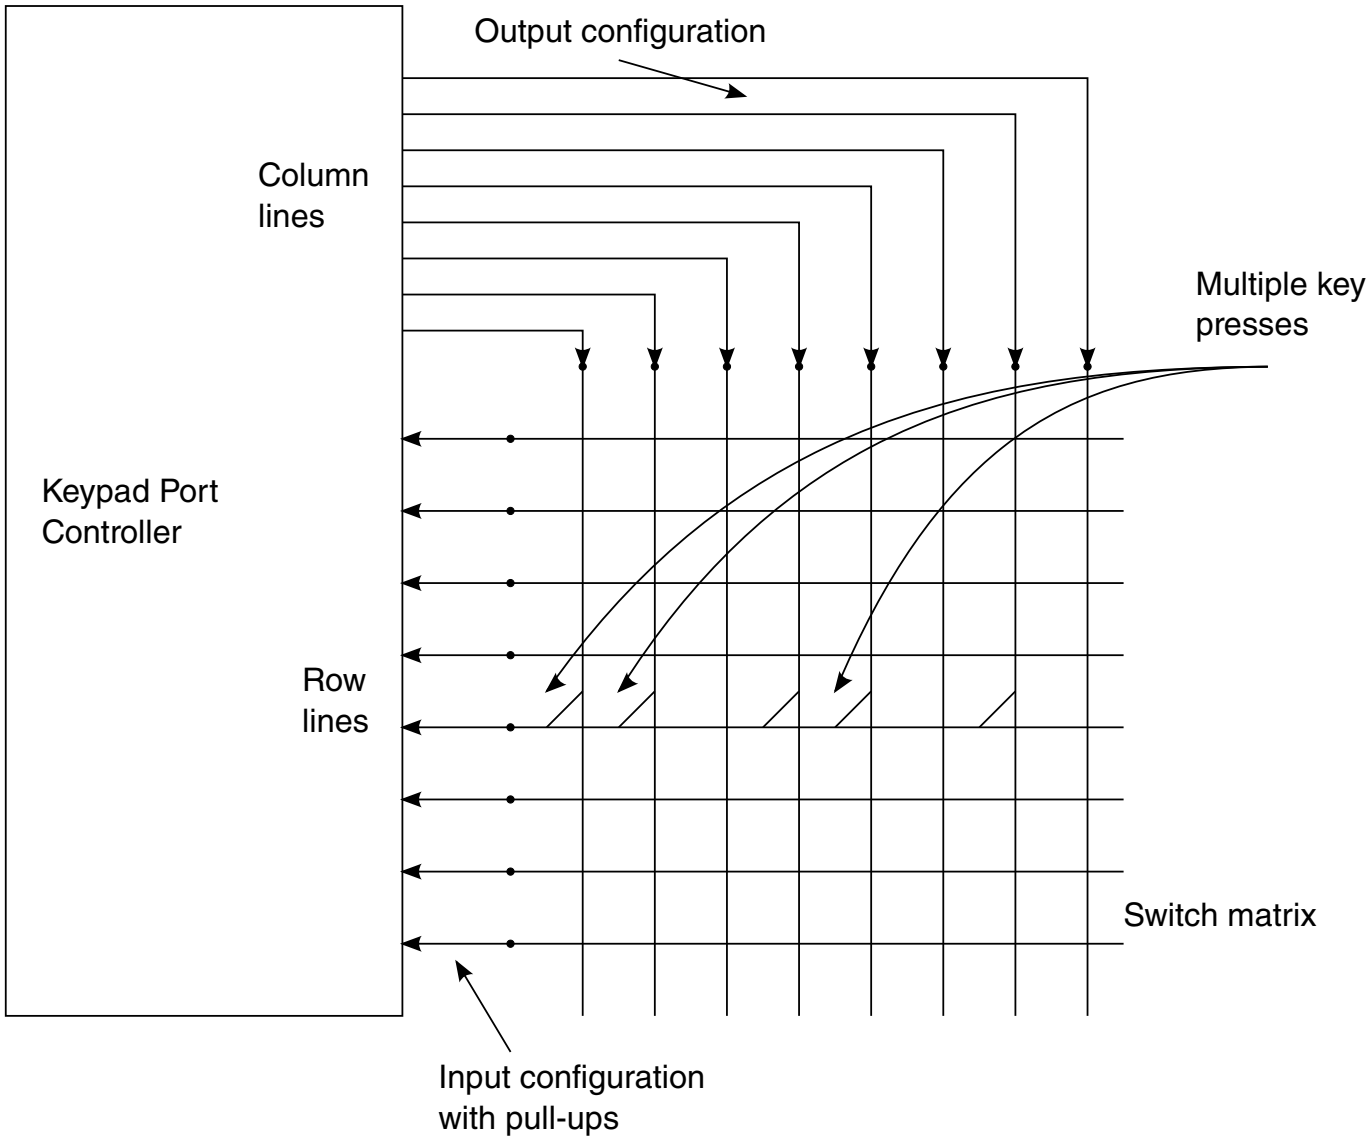

Figure 38-4. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

38.4.6.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As can be seen in Figure 38-5, three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 38-6).

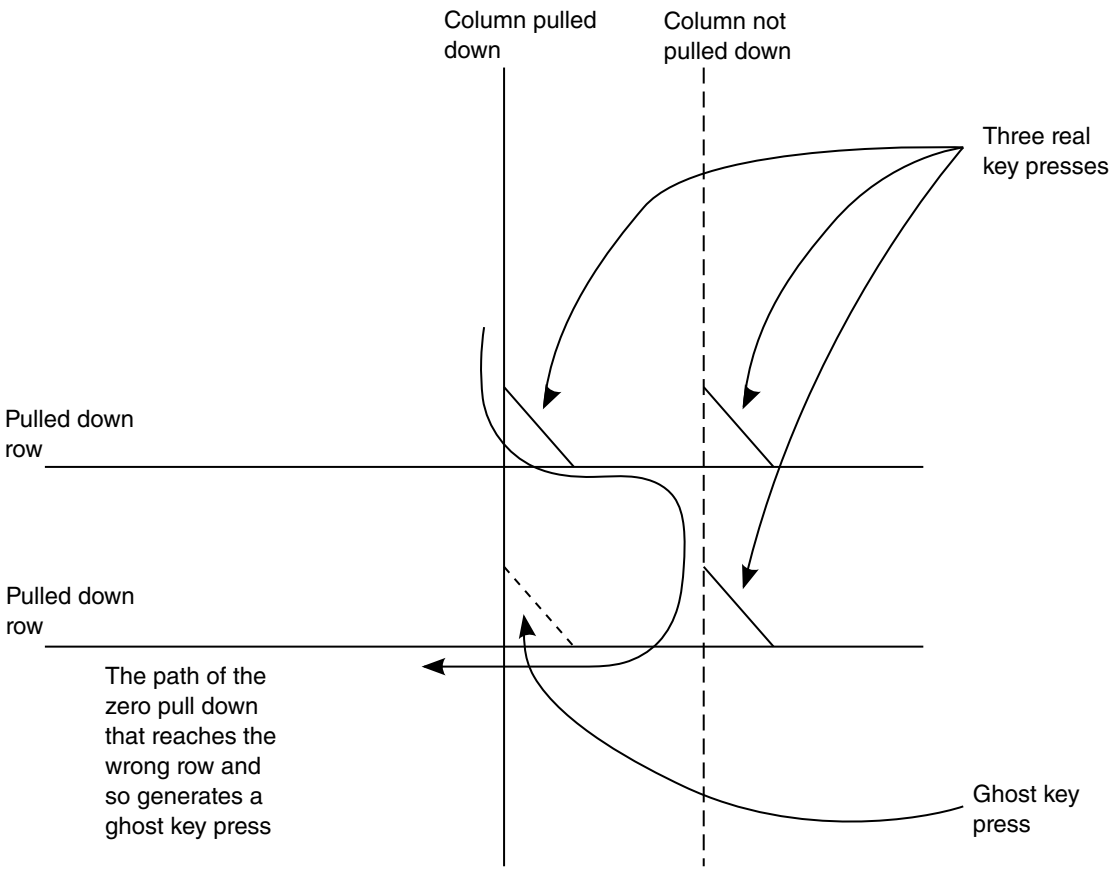

Figure 38-5. Decoding Wrong Three- Key-Presses

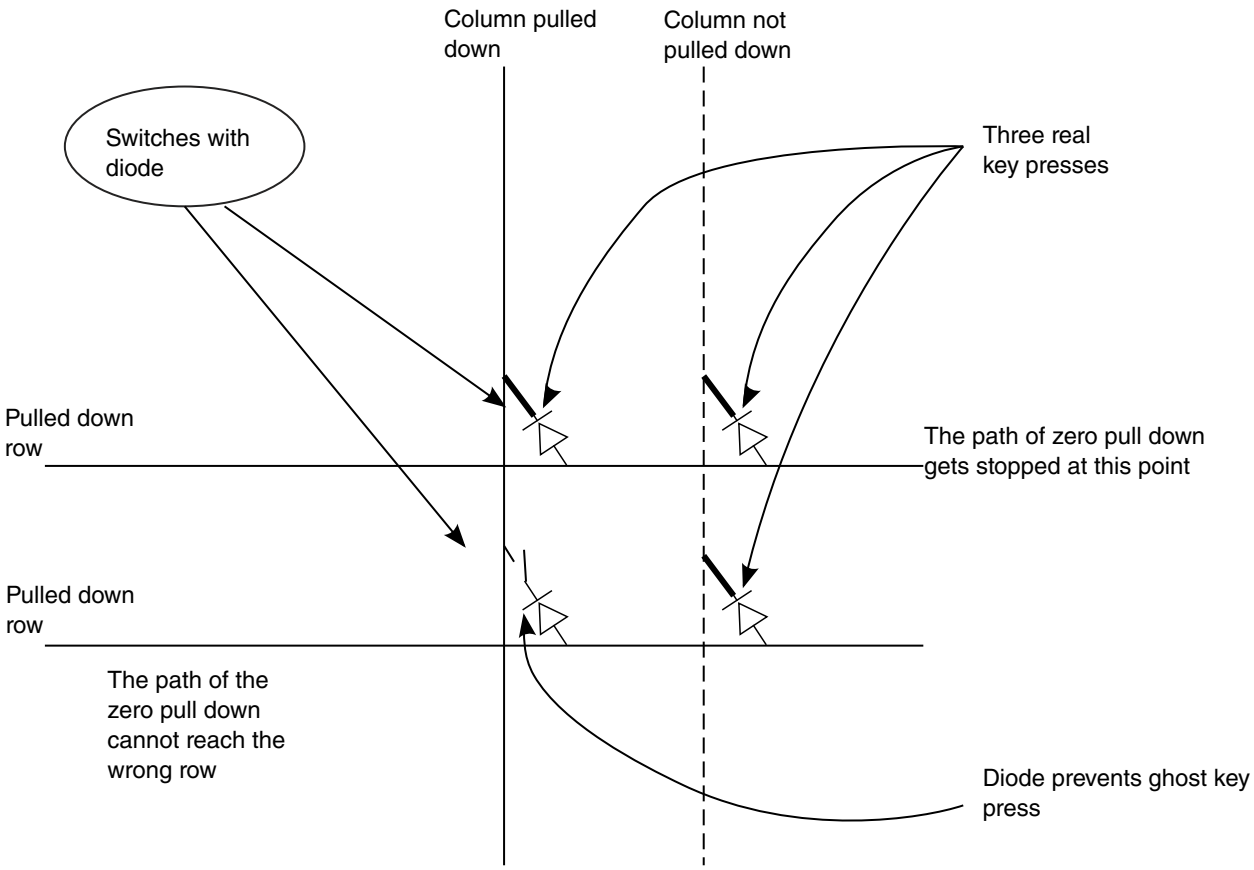

Figure 38-6. Matrix with "Ghost" Key Protections

38.4.7 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 38-7, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

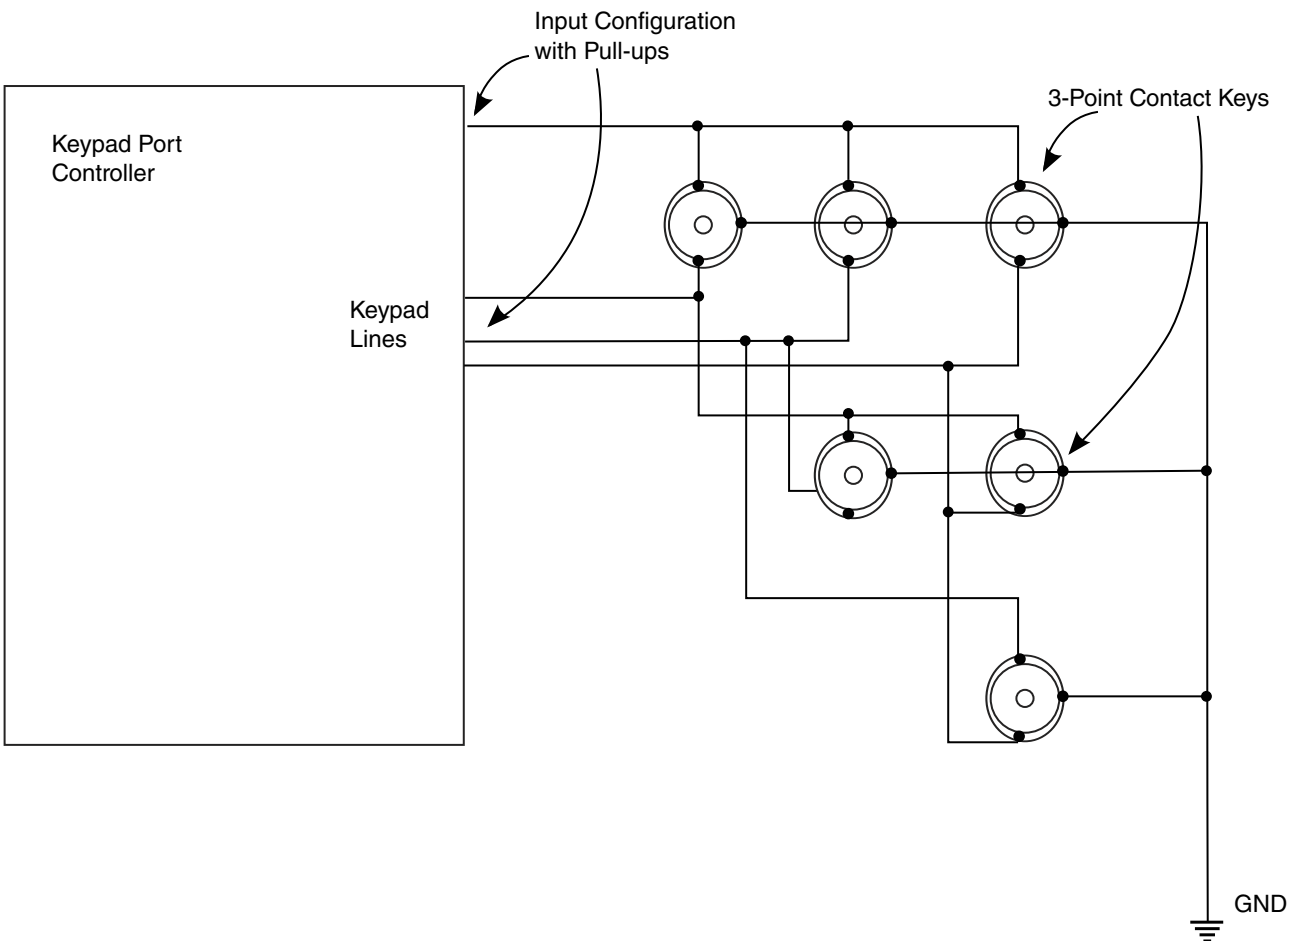

Figure 38-7. KPP Interface with 3-point Contact Key Matrix (Simplified View)

38.5 Initialization/Application Information

38.5.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP_KPCR[KRE]).
2. Write 0s to KPP_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP_KPCR[KCO]).
4. Configure columns as output (KPP_KDDR[KCDD]) and rows as input (KPP_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

38.5.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

38.5.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

38.6 KPP Memory Map/Register Definition

The KPP contains four registers.

KPP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20B_8000	Keypad Control Register (KPP_KPCR)	16	R/W	0000h	38.6.1/3548
20B_8002	Keypad Status Register (KPP_KPSR)	16	R/W	0400h	38.6.2/3549
20B_8004	Keypad Data Direction Register (KPP_KDDR)	16	R/W	0000h	38.6.3/3551
20B_8006	Keypad Data Register (KPP_KPDR)	16	R/W	0000h	38.6.4/3551

38.6.1 Keypad Control Register (KPP_KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP_KPCR register is byte- or half-word-addressable.

Address: 20B_8000h base + 0h offset = 20B_8000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCO								KRE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPCR field descriptions

Field	Description
15–8 KCO	Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input. **NOTE:** Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin. 0 **TOTEM_POLE** — Column strobe output is totem pole drive. 1 **OPEN_DRAIN** — Column strobe output is open drain.

Table continues on the next page...

KPP_KPCR field descriptions (continued)

Field	Description
KRE	Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 0 Row is not included in the keypad key press detect. 1 Row is included in the keypad key press detect.

38.6.2 Keypad Status Register (KPP_KPSR)

The Keypad Status Register reflects the state of the key press detect circuit. The KPP_KPSR register is byte- or half-word-addressable.

Address: 20B_8000h base + 2h offset = 20B_8002h

Bit	15	14	13	12	11	10	9	8
Read	0						KRIE	KDIE
Write								
Reset	0	0	0	0	0	1	0	0

Bit	7	6	5	4	3	2	1	0
Read	0				0	0	KPKR	KPKD
Write					KRSS	KDSC	w1c	w1c
Reset	0	0	0	0	0	0	0	0

KPP_KPSR field descriptions

Field	Description
15–10 Reserved	This read-only field is reserved and always has the value 0.
9 KRIE	Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKR is set. 1 An interrupt request is generated when KPKR is set.
8 KDIE	Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain.

Table continues on the next page...

KPP_KPSR field descriptions (continued)

Field	Description
	0 No interrupt request is generated when KPKD is set. 1 An interrupt request is generated when KPKD is set.
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 KRSS	Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit. Reads return a value of "0". 0 No effect 1 Set bits which sets keypad release synchronizer chain
2 KDSC	Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit. Reads return a value of "0". 0 No effect 1 Set bits that clear the keypad depress synchronizer chain
1 KPKR	Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1". 0 No key release detected 1 All keys have been released
0 KPKD	Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0 No key presses detected 1 A key has been depressed

38.6.3 Keypad Data Direction Register (KPP_KDDR)

The bits in the KPP_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP_KDDR register is byte- or half-word addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in KRDD is cleared.

Address: 20B_8000h base + 4h offset = 20B_8004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCDD								KRDD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KDDR field descriptions

Field	Description
15–8 KCDD	Keypad Column Data Direction Register. Setting a bit configures the corresponding COL*n* pin as an output (where *n* = 7 through 0). 0 **INPUT** — COLn pin is configured as an input. 1 **OUTPUT** — COLn pin is configured as an output.
KRDD	Keypad Row Data Direction. Setting a bit configures the corresponding ROW*n* pin as an output (where *n* = 7 through 0). 0 **INPUT** — ROWn pin configured as an input. 1 **OUTPUT** — ROWn pin configured as an output.

38.6.4 Keypad Data Register (KPP_KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

Address: 20B_8000h base + 6h offset = 20B_8006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCD								KRD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPDR field descriptions

Field	Description
15–8 KCD	Keypad Column Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to column ports 1 Read/Write "1" from/to column ports
KRD	Keypad Row Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to row ports 1 Read/Write "1" from/to row ports

Chapter 39
LVDS Display Bridge (LDB)

39.1 Overview

The LVDS Display Bridge (LDB) connects the IPU (Image Processing Unit) to an External LVDS Display Interface.

The purpose of the LDB is to support flow of synchronous RGB data from the IPU to external display devices through the LVDS interface. This support covers all aspects of these activities:

- Connectivity to relevant devices - Displays with LVDS receivers.
- Arranging the data as required by the external display receiver and by LVDS display standards.
- Synchronization and control capabilities.

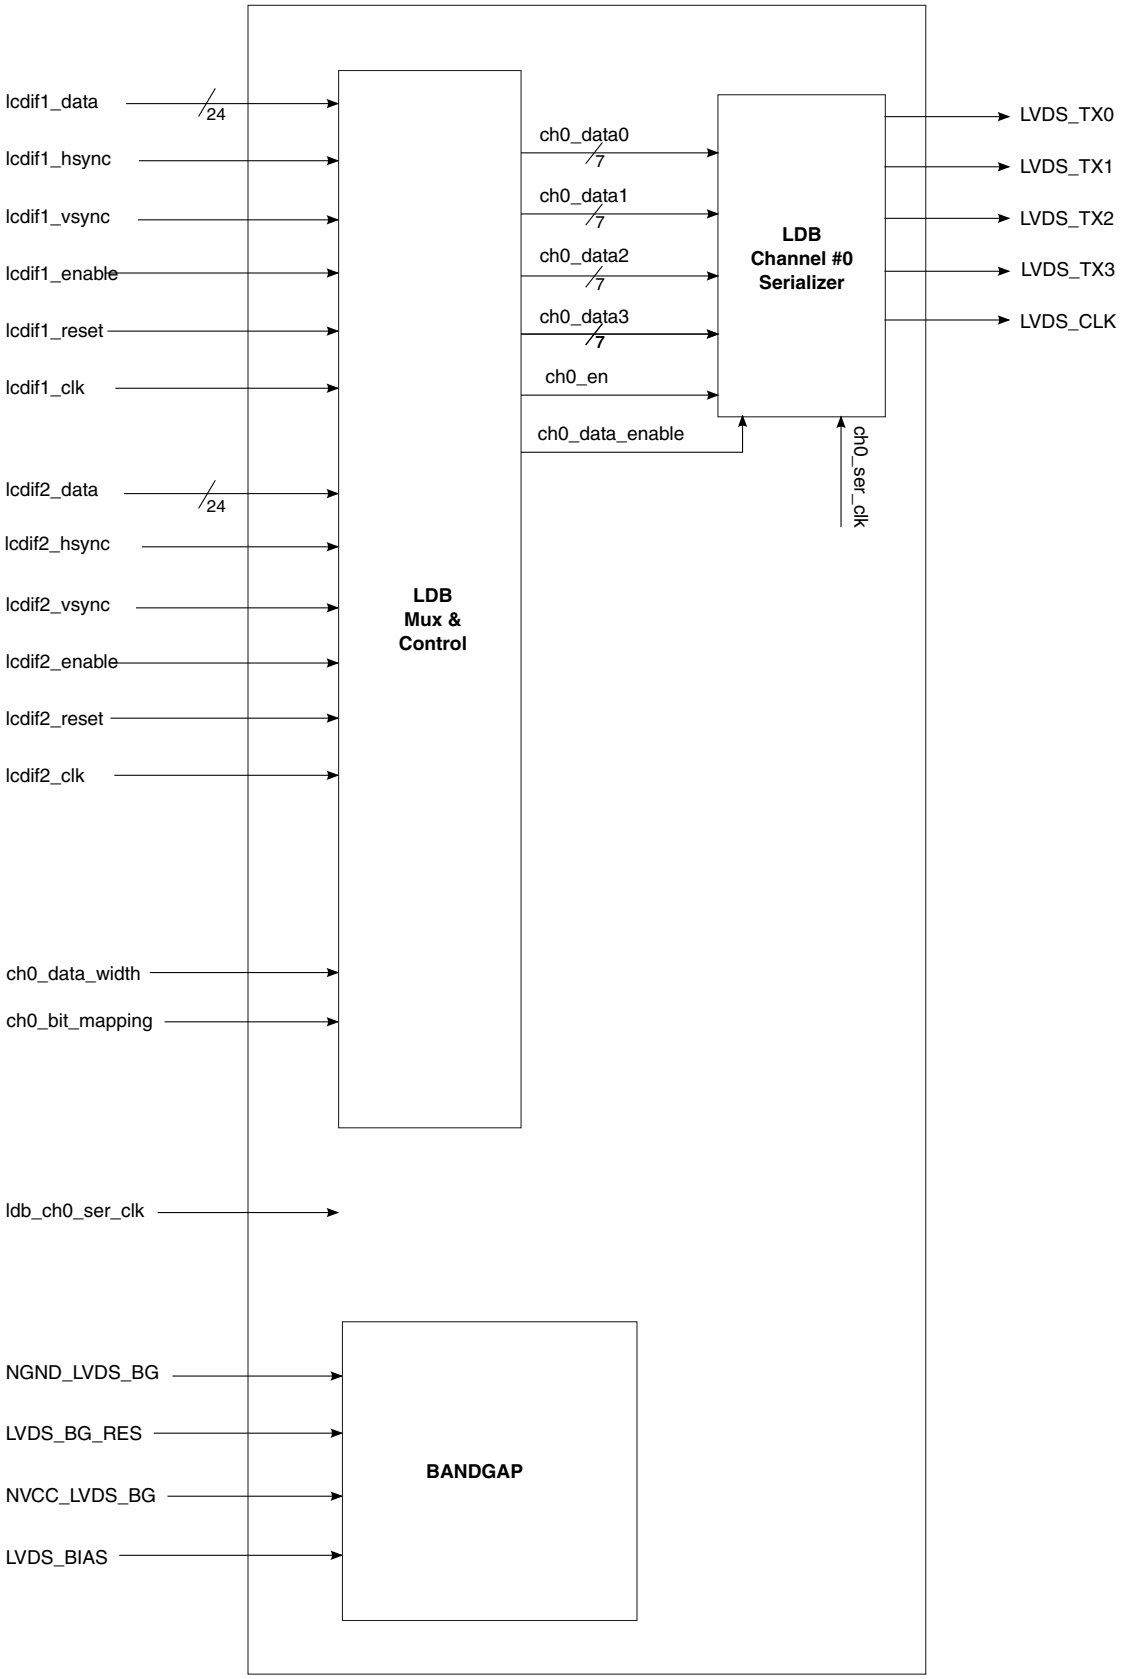

Figure 39-1. LDB Block Diagram

Table 39-1. LDB - Block Description

Block	Description
LDB Mux and Control	Gets control signals from SoC and determines parameters of LDB
Channel Serializers	LDB has 2 channel serializers. The serializer does parallel to serial conversion 7:1 to 3 or 4 data lines
Bandgap	Provides reference current to the LVDS I/O pads.

Table 39-2. LDB IP Parametric Table

Name	IPU
Function	Connectivity to displays with LVDS interface
External I/O Pins Those are LVDS I/O pads	LVDS Display port: 2 channels, consists of: • 1 clock pair • 4 data pairs Each pair contains - LVDS special differential pad (PadP, PadM). total of 20 I/O pads.
SoC Buses	None. Only configuration signals.
Interrupts	None
DMA Requests	None
Number of instantiations	1
Clock sources and range	IPU_DI0_CLK, IPU_DI1_CLK- Display interface clock: 20-170 MHz DI0_SERIAL_CLK, DI1_SERIAL_CLK - Serializer clock: 140-595 MHz

39.1.1 Relevant Standards

Below are the relevant standards to LDB:

1. ANSI EIA-644-A. Electrical Characteristics of Low Voltage Differential Signaling (LVDS) Interface Circuits.
2. SPWG Notebook Panel Specification (V3.8 from 03/2007) .
3. PSWG standards (Panel Standardization Working Group) - set of standards for panels using LVDS. All are available from http://www.vesa.org.
4. DISM Standard JEIDA-59-1999

39.2 External Signals

The following table describes the external signals of LDB:

Table 39-3. LDB External Signals

Signal	Description	Pad	Mode	Direction
LVDS0_CLK_N	LVDS0 Negative Clock Signal	LVDS0_CLK_N	No Muxing	I/O
LVDS0_CLK_P	LVDS0 Positive Clock Signal	LVDS0_CLK_P	No Muxing	I/O
LVDS0_DATA[3:0]_N	LVDS0 Negative Data Signals	LVDS0_TX[3:0]_N	No Muxing	I/O
LVDS0_DATA[3:0]_P	LVDS0 Positive Data Signals	LVDS0_TX[3:0]_P	No Muxing	I/O
LVDS1_CLK_N	LVDS1 Negative Clock Signal	LVDS1_CLK_N	No Muxing	I/O
LVDS1_CLK_P	LVDS1 Positive Clock Signal	LVDS1_CLK_P	No Muxing	I/O
LVDS1_DATA[3:0]_N	LVDS1 Negative Data Signals	LVDS1_TX[3:0]_N	No Muxing	I/O
LVDS1_DATA[3:0]_P	LVDS1 Positive Data Signals	LVDS1_TX[3:0]_P	No Muxing	I/O

39.3 Clocks

A table with the LDB Clock Sources can be found here.

Table 39-4. LDB Clock Sources

Name	Symbol	Source	Rate	Comments
IPU DI0 interface pixel clock	IPU_DI0_CLK	Clock control Module	Up to 170 MHz	See note below [1]
IPU DI1 interface pixel clock	IPU_DI1_CLK	Clock control Module	Up to 170 MHz	This input also goes to IPU DI1 as input. See note below
CH0 interface serializer clock	DI0_SERIAL_CLK	Clock control Module	Up to 595 MHz	This is x7 the rate of the DI0 interface pixel clock. See note below.
CH1 interface serializer clock	DI1_SERIAL_CLK	Clock control Module	Up to 595 MHz	This is x7 the rate of the DI1 interface pixel clock. See note below

1. In case of single-channel or separate-channels use-case, the IPU DI_CLK is identical to the LVDS DI_CLK. In case of dual-channel use-case, the IPU DI_CLK has x2 higher frequency than that of the LVDS DI_CLK. Still both need to be synchronized

39.4 Input and Output Ports

39.4.1 Input Parallel Display Ports

One or Two parallel RGB input ports are supported (configurable). Only synchronous access mode is supported.Each RGB data interface contains the following:

- RGB Data of 18 or 24 bits
- Pixel clock
- Control signals: HSYNC, VSYNC, DE, and 1 additional optional general purpose control.

Total of up to 28 bits per data interface are transferred per pixel clock cycle.

Rates supported:

- Overall: LDB supports rates needed by WUXGA 16:10 aspect ratio (1920 x 1200 @ 60 frames per second, data rate supported up to 170 MHz)
- For single input data interface case: Up to 170 MHz pixel clock (WUXGA 1920x1200)
- For dual input data interface case: Up to 85 MHz per interface. (WXGA 1366x768 @ 60 frames per second, 35% blanking).

39.4.2 Output LVDS Ports

There is 2 LVDS channels. The output of each is used to communicate RGB data and controls to external LCD displays.

The LVDS ports may be used as follows:

- Single channel output
- Dual channel output (one input source, two channels outputs for two displays)
- Split channel output (one input source, splitted to 2 channels on output)
- Separate 2 channel output (2 input sources from IPU).

The output LVDS port complies to the EIA-644-A standard.

39.5 Processing

LDB data processing stages are as follows:

- Receive input data from 1 or 2 (configurable) parallel input interfaces. 18/24 RGB data + up to 4 controls and map them to LVDS channels.
  - If needed (dual-channel) split the input bus to two half-rate busses.
- Re-arrange the input data according to channel configuration, and muxing scheme.
- Serialize the 22/28 bit input bus (per channel) on 3-4 output serial data lines (7:1)

39.5.1 Mapping of Input Data Busses

Mapping of Parallel input interfaces (DI0, DI1) to output LVDS channels (Channel 0, Channel 1). See Table 39-5.

Table 39-5. Channel Mapping

Use Case	LVDS Channel 0	LVDS Channel 1
Single Channel DI0	DI0	Disabled
Single Channel DI1 on Channel 1	Disabled	DI1
Separate Channels	DI0	DI1
Dual Channels DI0	DI0	DI0
Dual Channels DI1	DI1	DI1
Split Channel DI0	DI0 (first pixel)	DI0 (second pixel)
Split Channel DI1	DI1 (first pixel)	DI1 (second pixel)

39.5.2 Bit Mapping

LDB supports two mapping standards:

- SPWG mapping
- JEIDA mapping

Table 39-6. SPWG/PSWG/VESA 18/24 bpp Data Mapping

Serializer input	Slot 0	Slot 1	Slot 2	Slot 3	Slot 4	Slot 5	Slot 6
LVDSn_DATA0	G0	R5	R4	R3	R2	R1	R0
LVDSn_DATA1	B1	B0	G5	G4	G3	G2	G1
LVDSn_DATA2	DE	VS	HS	B5	B4	B3	B2
LVDSn_DATA3 (for 24 bpp only)	CTL	B7	B6	G7	G6	R7	R6

Table 39-7. JEIDA 24bpp Data Mapping

Serializer input	Slot 0	Slot 1	Slot 2	Slot 3	Slot 4	Slot 5	Slot 6
LVDSn_DATA0	G2	R7	R6	R5	R4	R3	R2
LVDSn_DATA1	B3	B2	G7	G6	G5	G4	G3
LVDSn_DATA2	DE	VS	HS	B7	B6	B5	B4
LVDSn_DATA3	CTL	B1	B0	G1	G0	R1	R0

NOTE

Several options of control usage can be available. some display devices use only DE, some others use all 3 controls, some use

only HS, VS. "CTL" is an optional general purpose control which is usually unused by display.

39.6 LDB Memory Map/Register Definition

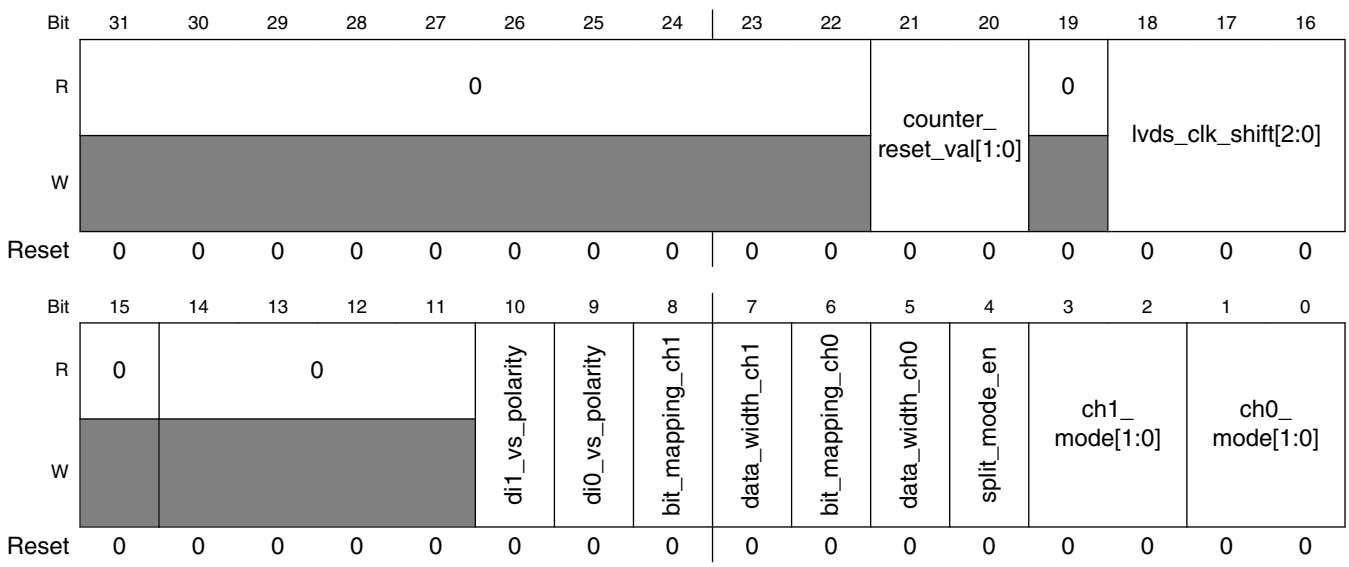
LDB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20E_0008	LDB Control Register (LDB_CTRL)	32	R/W	0000_0000h	39.6.1/3559

39.6.1 LDB Control Register (LDB_CTRL)

The register is implemented in the IOMUX Controller block (IOMUXC), as the register IOMUXC_GPR2.

Address: 20E_0008h base + 0h offset = 20E_0008h



LDB_CTRL field descriptions

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value 0.
21–20 counter_reset_val[1:0]	Reset value for the LDB counter which determines when the shift registers are loaded with data. **NOTE:** Used for debug purposes only. In normal functional operation must be '00'

Table continues on the next page...

LDB_CTRL field descriptions (continued)

Field	Description
	00 Reset value is 5 01 Reset value is 3 10 Reset value is 4 11 Reset value is 6
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 lvds_clk_shift[2:0]	Shifts the LVDS output clock in relation to the data. **NOTE:** Used for debug purposes only. In normal functional operation must be '000' 000 Output clock is '1100011' (normal operation) 001 Output clock is '1110001' 010 Output clock is '1111000' 011 Output clock is '1000111' 100 Output clock is '0001111' 101 Output clock is '0011111' 110 Output clock is '0111100' 111 Output clock is '1100011'
15 Reserved	This read-only field is reserved and always has the value 0.
14–11 Reserved	This read-only field is reserved and always has the value 0.
10 di1_vs_polarity	Vsync polarity for IPU's DI1 interface. 0 ipu_di1_vsync is active high. 1 ipu_di1_vsync is active low.
9 di0_vs_polarity	Vsync polarity for IPU's DI0 interface. 0 ipu_di0_vsync is active high. 1 ipu_di0_vsync is active low.
8 bit_mapping_ch1	Data mapping for LVDS channel 1. 0 Use SPWG standard. 1 Use JEIDA standard.
7 data_width_ch1	Data width for LVDS channel 1. **NOTE:** This bit must be set when using JEIDA standard (bit_mapping_ch1 is set) 0 Data width is 18 bits wide (lvds1_tx3 is not used) 1 Data width is 24 bits wide.
6 bit_mapping_ch0	Data mapping for LVDS channel 0. 0 Use SPWG standard. 1 Use JEIDA standard.
5 data_width_ch0	Data width for LVDS channel 0. **NOTE:** This bit must be set when using JEIDA standard (bit_mapping_ch0 is set) 0 Data width is 18 bits wide (lvds0_tx3 is not used) 1 Data width is 24 bits wide.

Table continues on the next page...

LDB_CTRL field descriptions (continued)

Field	Description
4 split_mode_en	Enable split mode. **NOTE:** In this mode both channels should be enabled and working with the same DI (ch0_mode and ch1_mode should both be either '01' or '11') 0 Split mode is disabled. 1 Split mode is enabled.
3–2 ch1_mode[1:0]	LVDS channel 1 operation mode 00 Channel disabled. 01 Channel enabled, routed to DI0 10 Channel disabled. 11 Channel enabled, routed to DI1.
ch0_mode[1:0]	LVDS channel 0 operation mode 00 Channel disabled. 01 Channel enabled, routed to DI0 10 Channel disabled. 11 Channel enabled, routed to DI1.

Chapter 40
MIPI - Camera Serial Interface Host Controller (MIPI_CSI)

40.1 Overview

The CSI-2 Host Controller is a digital core that implements all protocol functions defined in the MIPI CSI-2 Specification, providing an interface between the System and the MIPI D-PHY, allowing the communication with a MIPI CSI-2 compliant Camera Sensor.

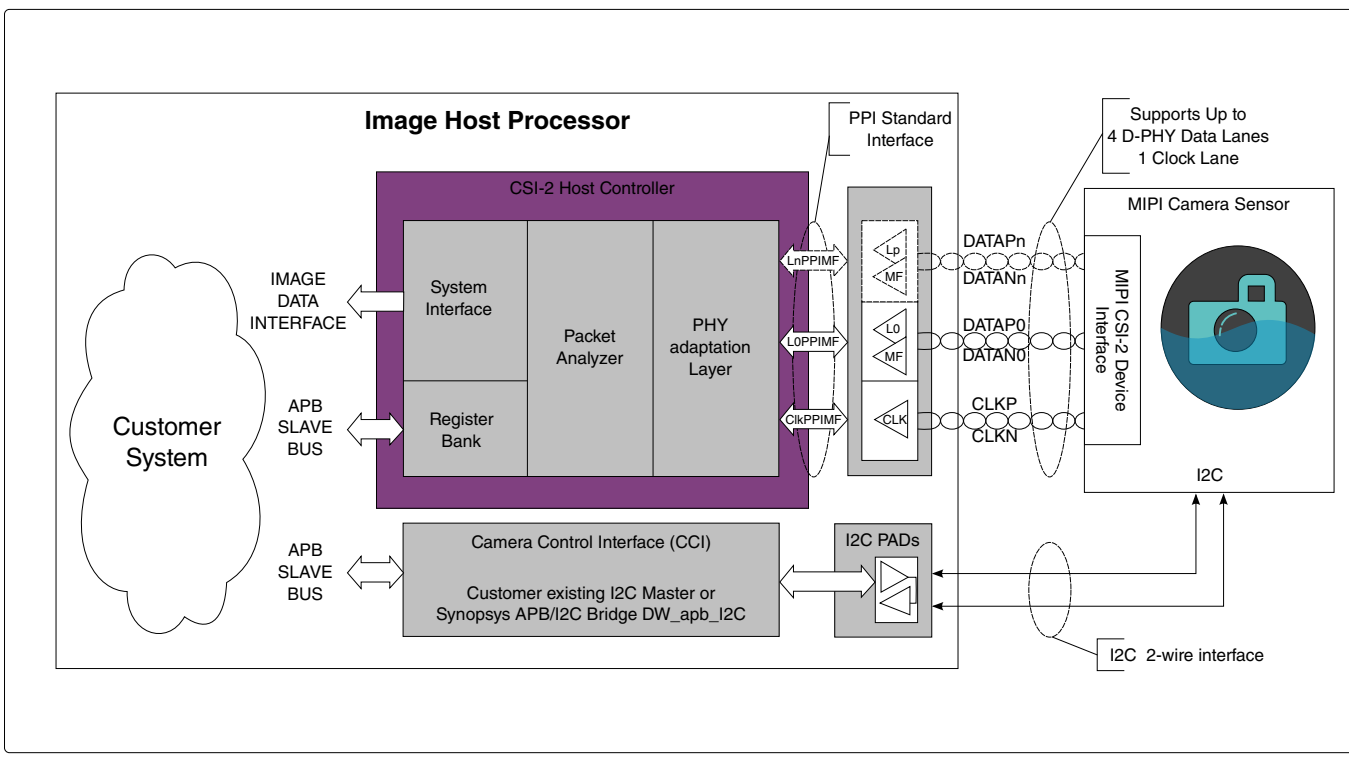


Figure 40-1. Block Diagram presenting the CSI-2 Host Controller function.

40.2 Features

The MIPI CSI-2 Host Controller supports the following features:

- Compliant with MIPI Alliance Standard for Camera Serial Interface 2 (CSI-2), Version 1.00 - 29 November 2005
- Interface with MIPI D-PHY following PHY Protocol Interface (PPI), as defined in MIPI Alliance Specification for D-PHY, Version 1.00.00 - 14 May 2009
- Supports up to 4 D-PHY Rx Data Lanes
- Dynamically configurable multi-lane merging
- Long and Short packet decoding
- Timing accurate signaling of Frame and Line synchronization packets
- Support for several frame formats such as:
  - General Frame or Digital Interlaced Video with or without accurate sync timing
  - Data type (Packet or Frame level) and Virtual Channel interleaving
- 32-bit Image Data Interface delivering data formatted as recommended in CSI-2 Specification;
- Supports all primary and secondary data formats:
  - RGB, YUV and RAW color space definitions
  - From 24-bit down to 6-bit per pixel
  - Generic or user-defined byte-based data types
- Error detection and correction:
  - PHY level
  - Packet level
  - Line level
  - Frame level

40.3 Architecture

The following figure presents the overall architecture of the CSI-2 Host Controller. The main blocks are the following:

- PHY Adaptation Layer, which is responsible for managing the D-PHY interface, including PHY error handling;
- Packet Analyzer, where data lane merging is implemented if required, together with header decoding, error detection and correction, frame size error detection and CRC error detection;
- Image Data Interface. This block separates CSI-2 packet header information and reorders data according to memory storage format, and it also generates timing

accurate video synchronization signals. Several error detections are also performed at frame-level and line-level;

- Register Bank, accessible through a standard AMBA-APB slave interface, providing access to the CSI-2 Host Controller registers for configuration and control. There is also a fully programmable interrupt generator to inform the system upon certain events;

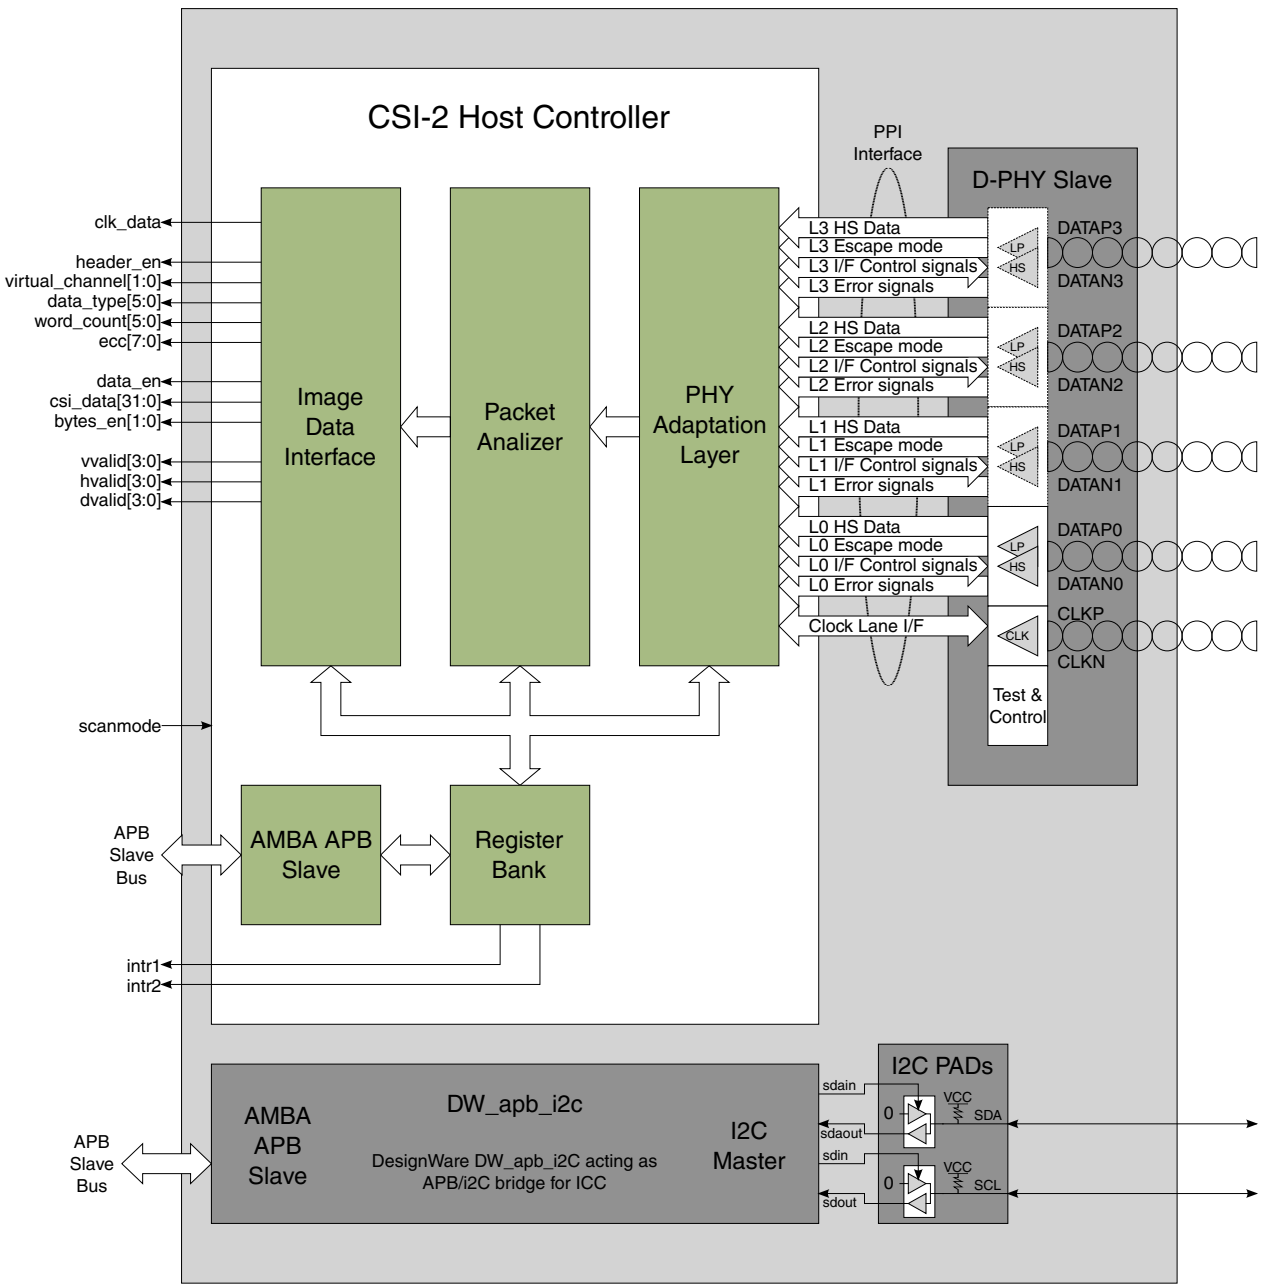

Figure 40-2. Architecture of the CSI-2 Host Controller.

40.3.1 Startup Sequence

The following information is provided as a guideline to allow a safe startup of the system operation.

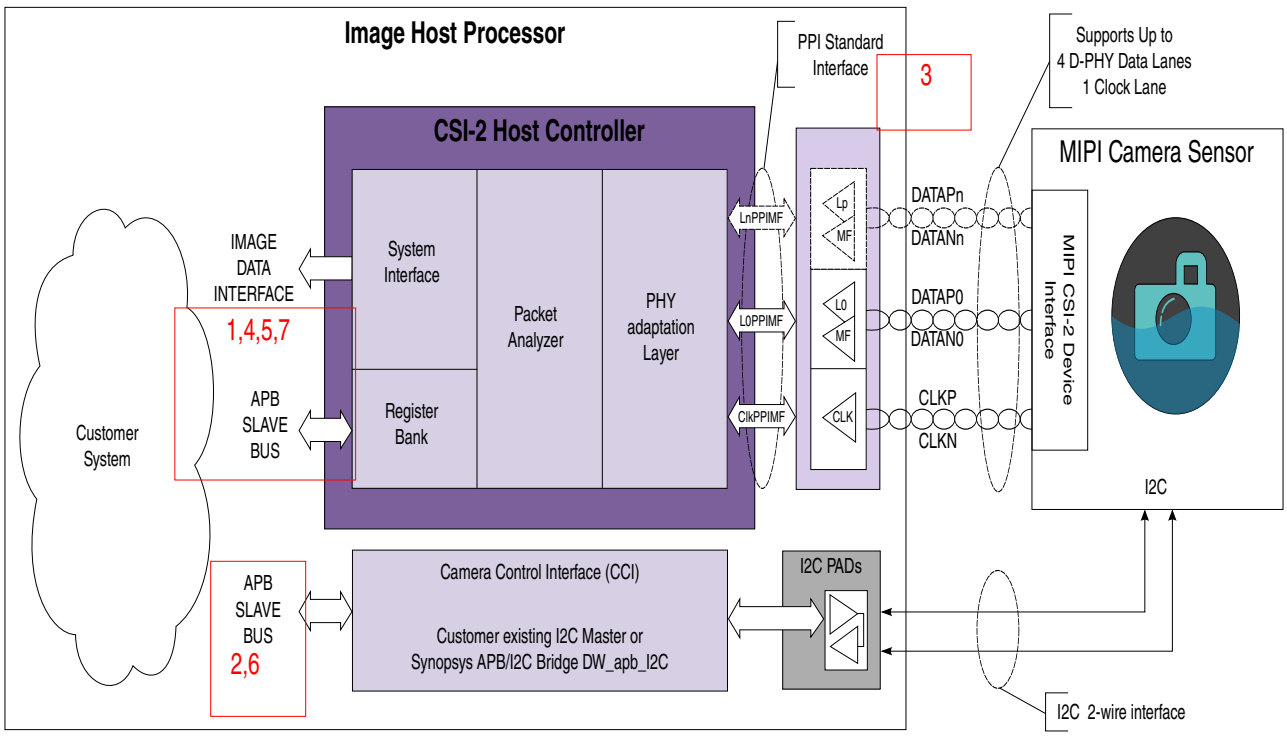

Figure 40-3. Block diagram presenting the recommended Startup Sequence.

1. Deassert CSI2 presetn signal (global reset);
2. **Configure MIPI Camera Sensor to have all Tx lanes in PL-11 state (STOPSTATE) if required** - According to D-PHY Specification the D-PHY master should be initialized at LP-11 state (STOPSTATE), nevertheless a CCI command may be required to switch-on the MIPI interface;
3. **D-PHY initialization** - Access the D-PHY programming interface to initialize and program the D-PHY according to the selected operating mode of the D-PHY. This is D-PHY dependent, and this programming should be carried out according to the D-PHY databook;
4. **CSI2 Controller programming** - Program the CSI2 Host Controller registers according to the operating mode required:
   - **Number of Lanes (register N_LANES);**
   - **Deassert PHY shutdown (register PHY_SHUTDOWNZ);**
   - **Deassert PHY reset (register PHY_RSTZ);**
   - **Deassert CSI reset (register CSI2_RESETN);**

- **(Optional) Program Data IDs for matching error reporting (registers DATA_IDS_1 and DATA_IDS_2);**
- **(Optional) Program the interrupt masks (registers MASK1 and MASK2);**

5. **CSI2 Controller programming** - Read the PHY status register (PHY_STATE) to confirm that all data and clock lanes of the D-PHY are in Stop State (i.e. ready to receive data);
6. **Configure the MIPI Camera Sensor** - Access Camera Sensor using CCI interface to initialize and configure the Camera Sensor to start transmitting a clock on the D-PHY clock lane;
7. **CSI2 Controller programming** - Read the PHY status register (PHY_STATE) to confirm that the D-PHY is receiving a clock on the D-PHY clock lane;

NOTE

Additional steps may be required to correctly configure the specific D-PHY and MIPI Camera Sensor(s) that are part of the system, as well as any other requirements that is integral part of the relevant MIPI Specifications.

40.3.2 Interrupt mechanism

The CSI-2 Host Controller provides an interrupt mechanism that is usable mostly for monitoring errors and debugging.

There are two interrupt signals, *intr1* and *intr2*, which are synchronous with the AMBA-APB clock signal. Registers MASK1 and MASK2 are used to select which bits of registers ERR1 and ERR2 are able to generate interrupts by asserting signals *intr1* and *intr2*, respectively. Both ERR1 and ERR2 will always contain the information of events, irrespective of the state of MASK1 and MASK2. Registers ERR1 and ERR2 will self-clear after a read access. Interrupt signals *intr1* and *intr2* will be de-asserted upon read access of register ERR1 and ERR2, respectively.

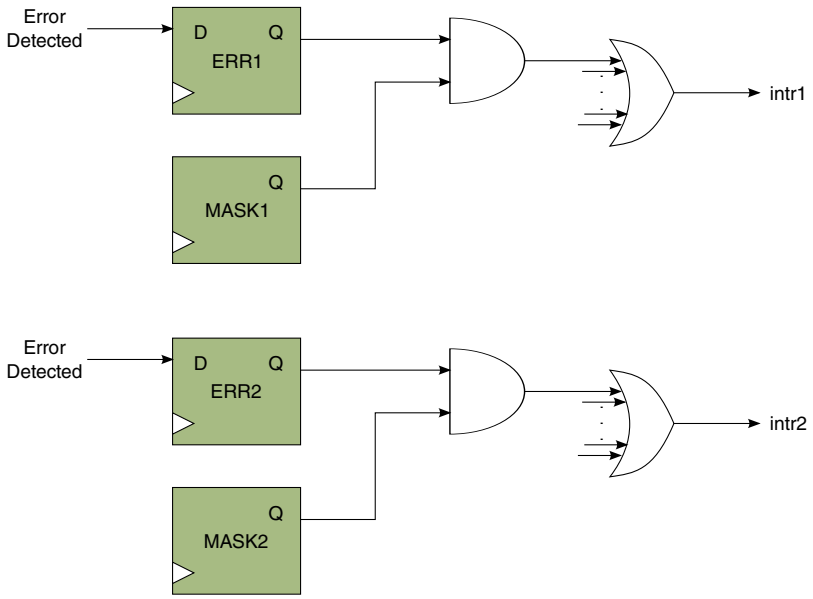

Figure 40-4. Block Diagram presenting the Interrupt mechanism.

40.3.3 Signals

Table 40-1. D-PHY External interface signals

Pin Name	Width	Direction	Description
AVDD	1	Input	D-PHY Analog power supply.
VDD	1	Input	D-PHY Digital power supply.
AVDDREF	1	Input	D-PHY Analog supply for reference generator.
AGND	1	Input	D-PHY Analog supply ground return.
VSS	1	Input	D-PHY Digital supply ground return.
AGNDREF	1	Input	D-PHY Analog supply ground return for reference generator.
REXT	1	Input	D-PHY External resistor connection (REXT should be shorted at the chip pad connection).
CSI2_CLKP	1	Input	D-PHY Positive D-Phy differential clock line Receiver input
CSI2_CLKN	1	Input	D-PHY Negative D-Phy differential clock line Receiver input
CSI2_DATAP0	1	Input	D-PHY Positive D-Phy differential data line Receiver input , Lane 0
CSI2_DATAN0	1	Input	D-PHY Negative D-Phy differential data line Receiver input , Lane 0
CSI2_DATAP1	1	Input	D-PHY Positive D-Phy differential data line Receiver input , Lane 1
CSI2_DATAN1	1	Input	D-PHY Negative D-Phy differential data line Receiver input , Lane 1

Table continues on the next page...

Table 40-1. D-PHY External interface signals (continued)

CSI2_DATAP2	1	Input	D-PHY Positive D-Phy differential data line Receiver input , Lane 2
CSI2_DATAN2	1	Input	D-PHY Negative D-Phy differential data line Receiver input , Lane 2
CSI2_DATAP3	1	Input	D-PHY Positive D-Phy differential data line Receiver input , Lane 3
CSI2_DATAN3	1	Input	D-PHY Negative D-Phy differential data line Receiver input , Lane 3

40.4 Timing Interfaces

40.4.1 Image Data Interface

At the Image Data Interface, signal *header_en* is used to indicate that new data is being transferred. It rises when a new packet becomes available at the interface and falls as soon as a packet finishes. Between two consecutive packets, there is always a fall and a rise of *header_en*, since the CSI-2 transmitter must enter Low-Power State between an End of Transmission and the following Start of Transmission.

An example of transferring two short packets is presented in the following figure. The fields of the header packet become available simultaneously to the rise of *header_en*, which falls after one clock cycle, as no new data is to be transferred. This is the behavior of the circuit, independently of the number of active lanes.

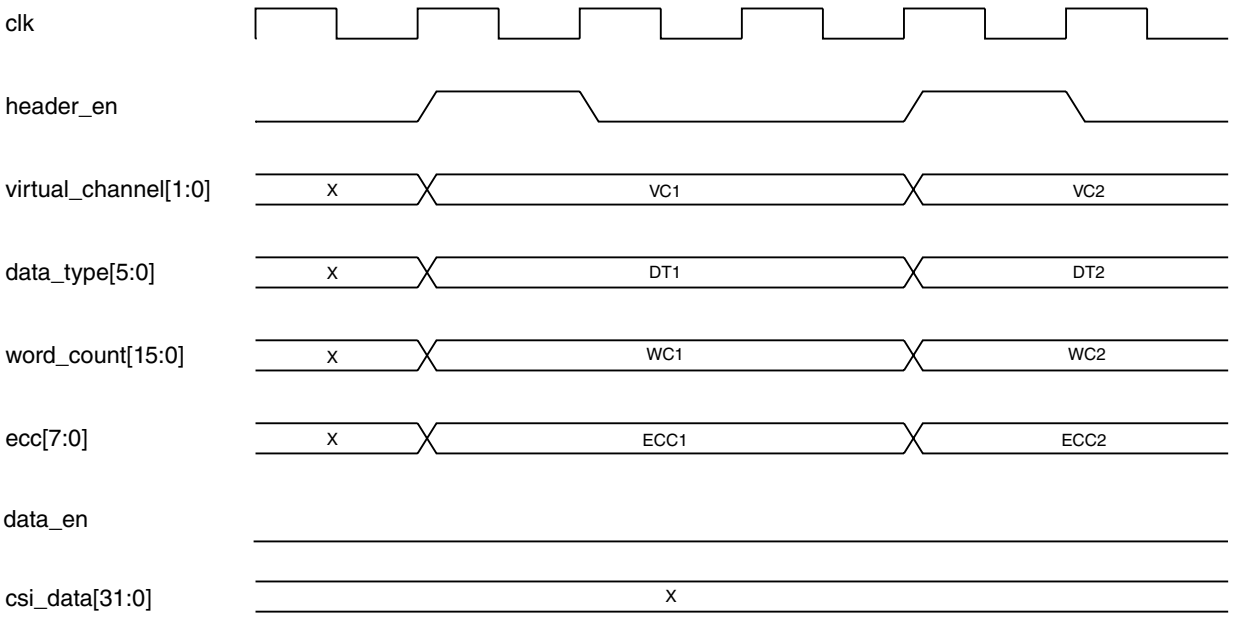

Figure 40-5. Image Data Interface example with two short packets.

When transferring long packets, the data provided by the payload on all lanes is transferred separately on *csi_data* bus, while the header fields remain stable until the transfer of the packet has completed.

Signal *data_en* is used to indicate that a new 32-bit word is available in *csi_data*, and it can only be set if *header_en* is also set. The following Figure shows an example of transferring a long packet received from 4 data lanes. Since a new 32-bit word is transferred at each clock cycle, signal *data_en* remains set until all data is transferred.

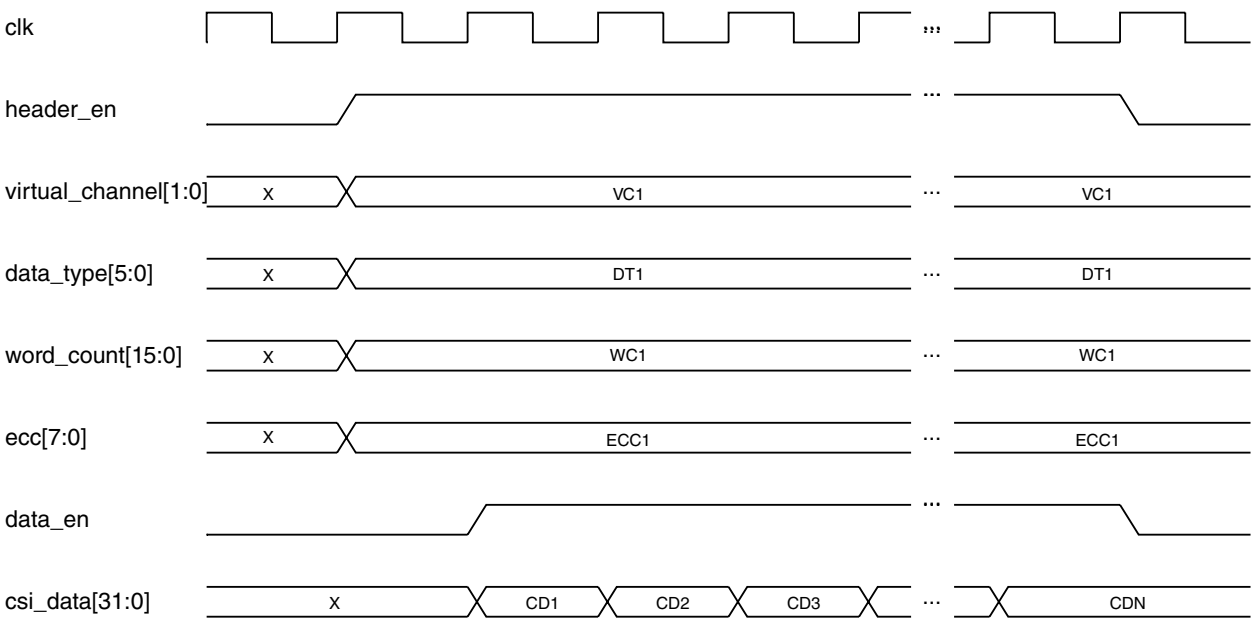

Figure 40-6. Timing interface for a long packet, receiving data from 4 lanes.

If less than 4 lanes are used, a 32-bit word might take more than one clock cycle to be received. In this case, *data_en* is set only when a new word has been fully received and becomes available at the interface. As shown in the following figure, when data is received from two lanes a new word is released every two clock cycles. Both *header_en* and *data_en* return to 0 as soon as all the data has been transferred.

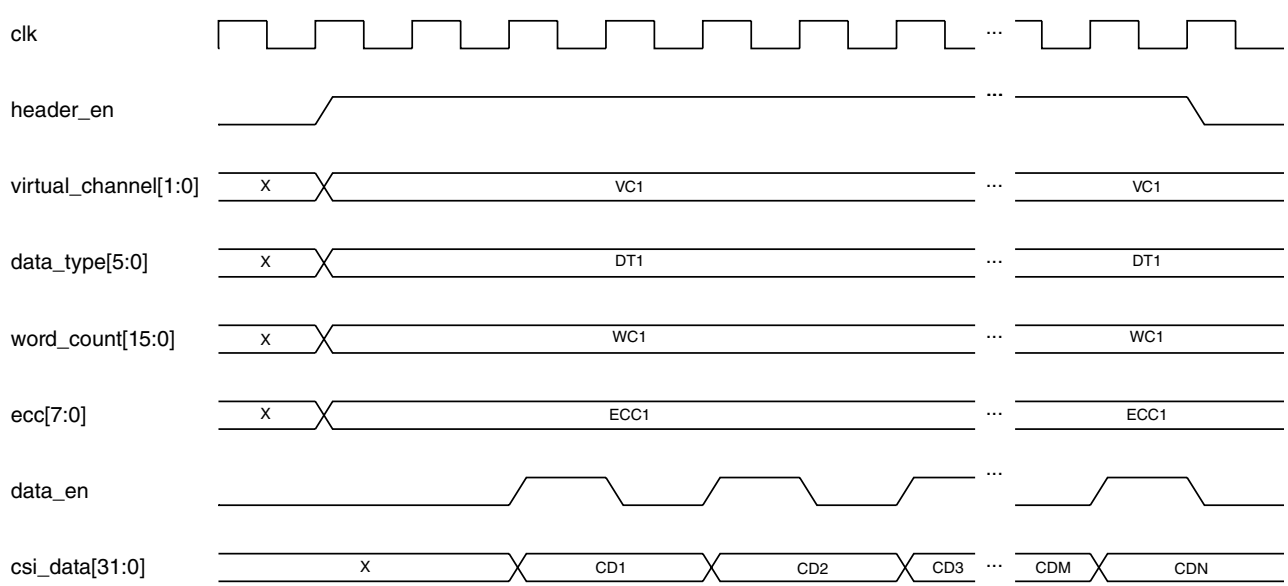

Figure 40-7. Timing interface for a long packet, receiving data from 2 lanes.

If data is transferred using only 1 lane, a new 32-bit word becomes available every four clock cycles. In the case of 3 lanes, a new word is available at clock cycle except every fourth.

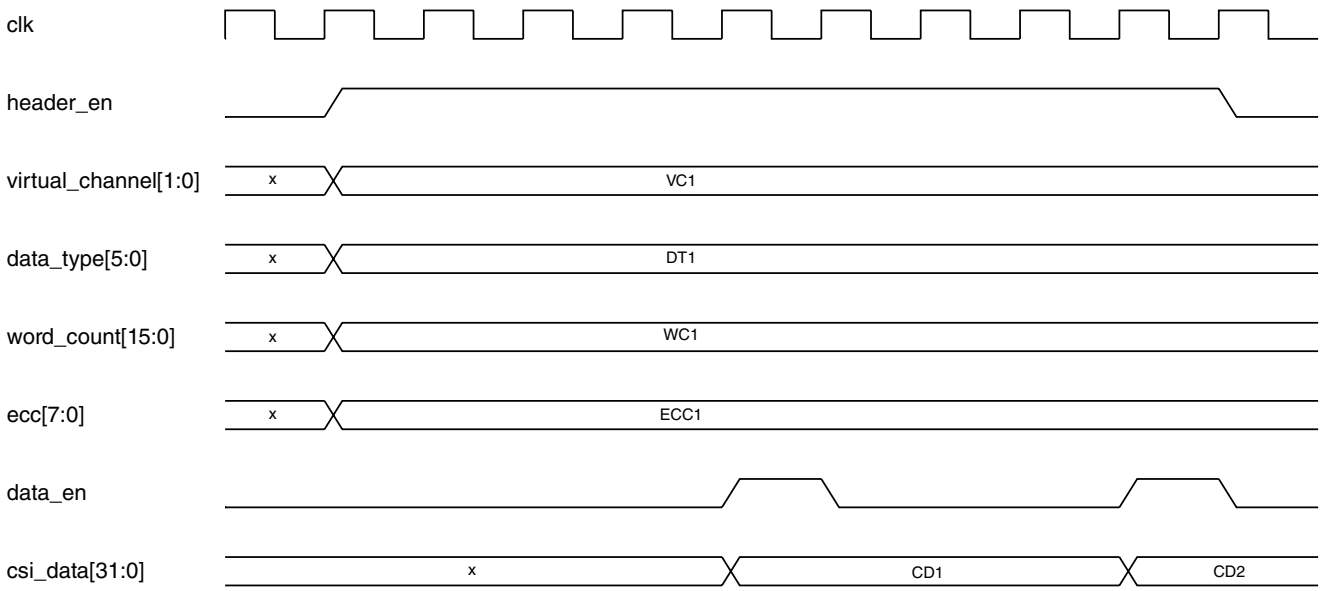

Figure 40-8. Timing interface for a long packet, receiving data from 1 lane.

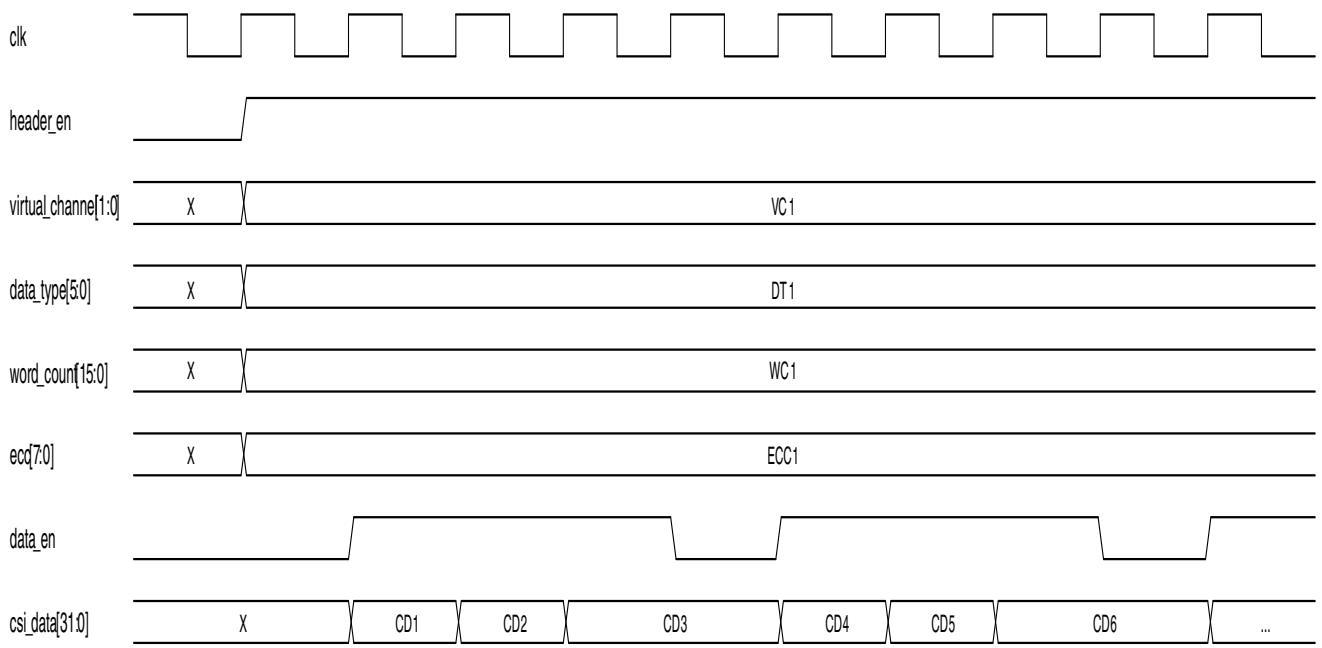

Figure 40-9. Timing interface for a long packet, receiving data from 3 lanes.

Signals *dvalid*, *hvalid* and *vvalid*, are used provide information about Frame Start, Frame End, Line Start and Line End packets. These signals are included in the interface for synchronization purposes.

dvalid is used to indicate when data is being transferred, excluding header information. Data sent through Blank or Null packets do not activate *dvalid*.

hvalid is set on detection of Line Start packets and unset by Line End ones. These packets can be used as a reference for synchronization, even though relevant data can be more or less delayed between them, as it might be surrounded by Blanking Periods, before and after the data. Because Line Start and Line End packets are optional, in case they are not available, *hvalid* adopts the same behavior of *dvalid*, and is not activated by Blank or Null packets. In the case a new Line Start packet is received without a Line End packet being received, a pulse will be generated in *hvalid* to signal that a new Line Start packet was received.

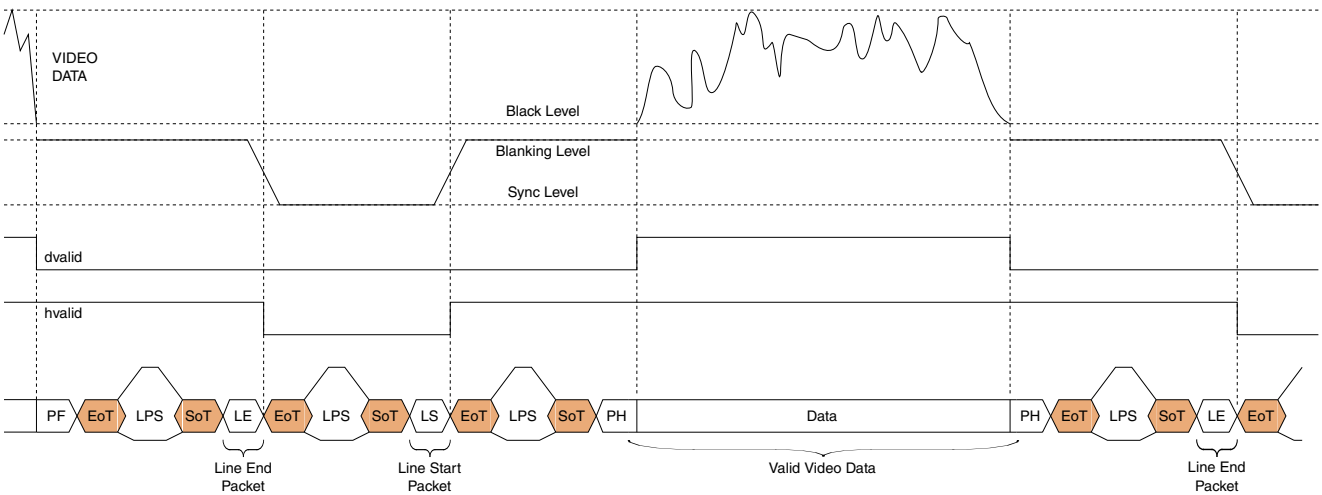

Figure 40-10. HVALID synchronization signal.

vvalid is set on detection of Frame Start packets and unset by Frame End ones. As these packets are mandatory, *vvalid* is always reliable for video applications to synchronize frame updating. In the case a new Frame Start packet is received without a Frame End packet being received, a pulse will be generated in *hvalid* to signal that a new Frame Start packet was received.

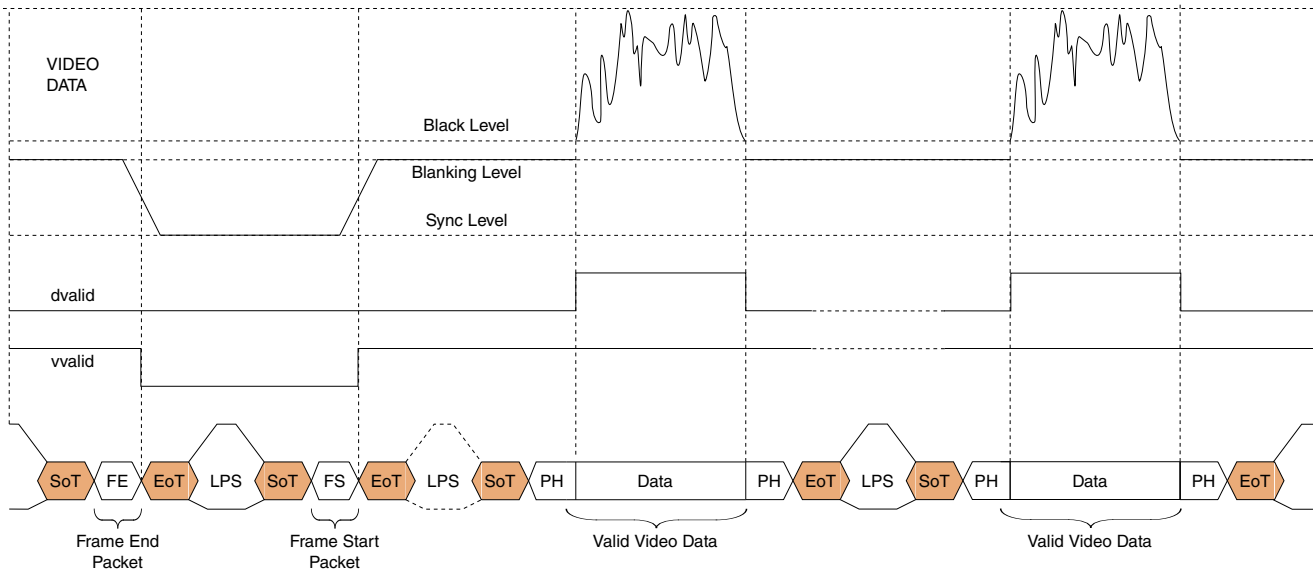

Figure 40-11. VVALID synchronization signal.

40.5 Payload Data Output Format

The Image Data Interface delivers payload data in a common data storage format, as suggested in CSI-2 Specification and described below.

The following sections describe how different data formats are transferred in output bus *csi_data*.

40.5.1 General/Arbitrary Data Reception

In the generic case and for arbitrary data, the first byte of payload data transmitted maps the least significant byte of the 32-bit memory word and the fourth byte of payload data transmitted maps to the most significant byte of the 32-bit memory word.

The following Figure illustrates the generic CSI-2 byte to 32-bit memory word mapping rule.

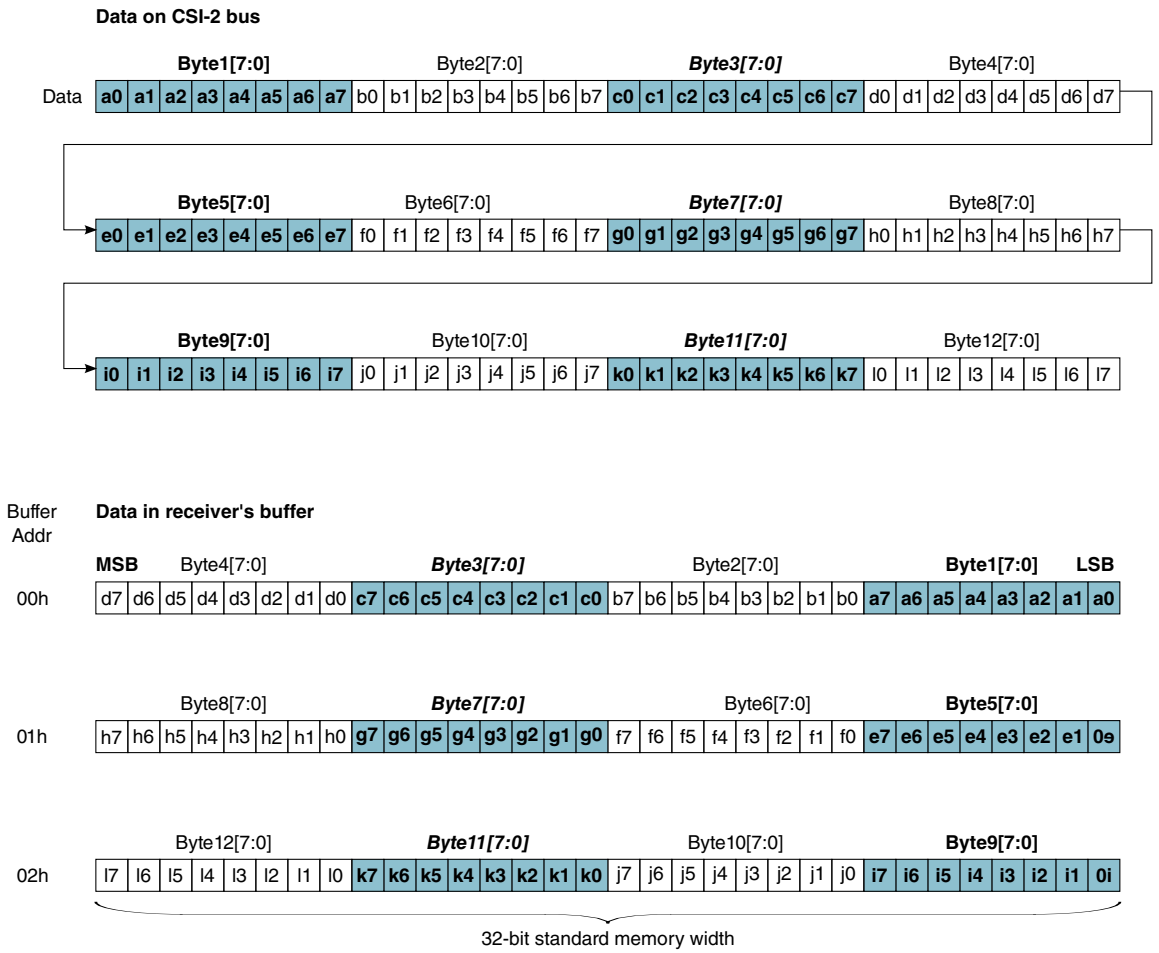

Figure 40-12. General/Arbitrary Data Reception.

40.5.2 RGB888 Data Reception

The RGB888 data format byte to 32-bit memory word mapping follows the generic CSI-2 rule.

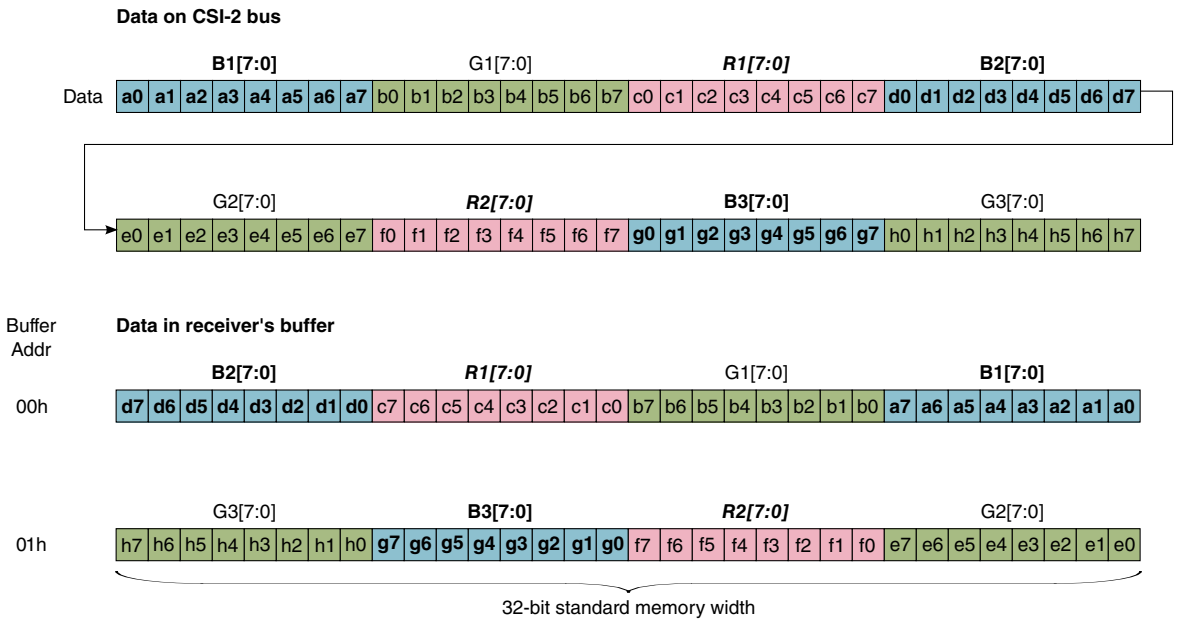

Figure 40-13. RGB888 Data Format Reception.

40.5.3 RGB666 Data Reception

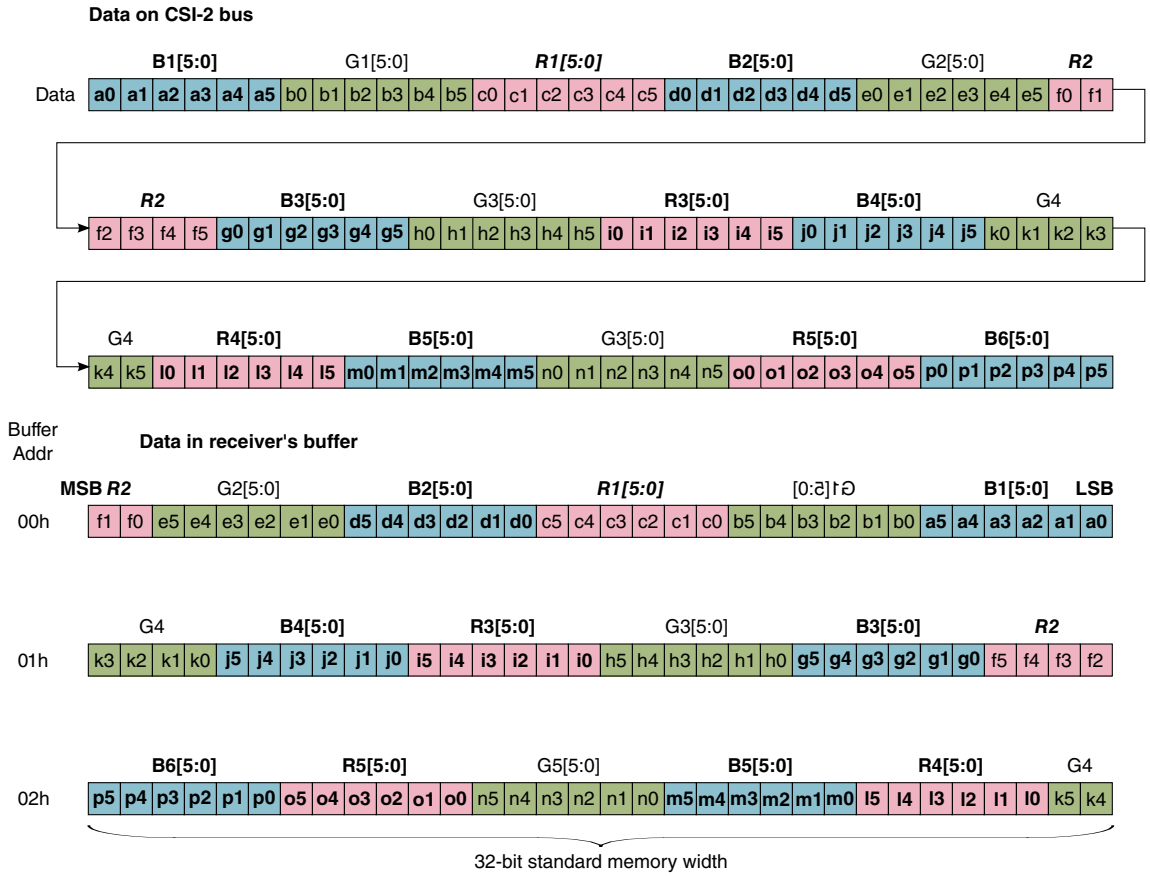

Figure 40-14. RGB666 Data Format Reception.

40.5.4 RGB565 Data Reception

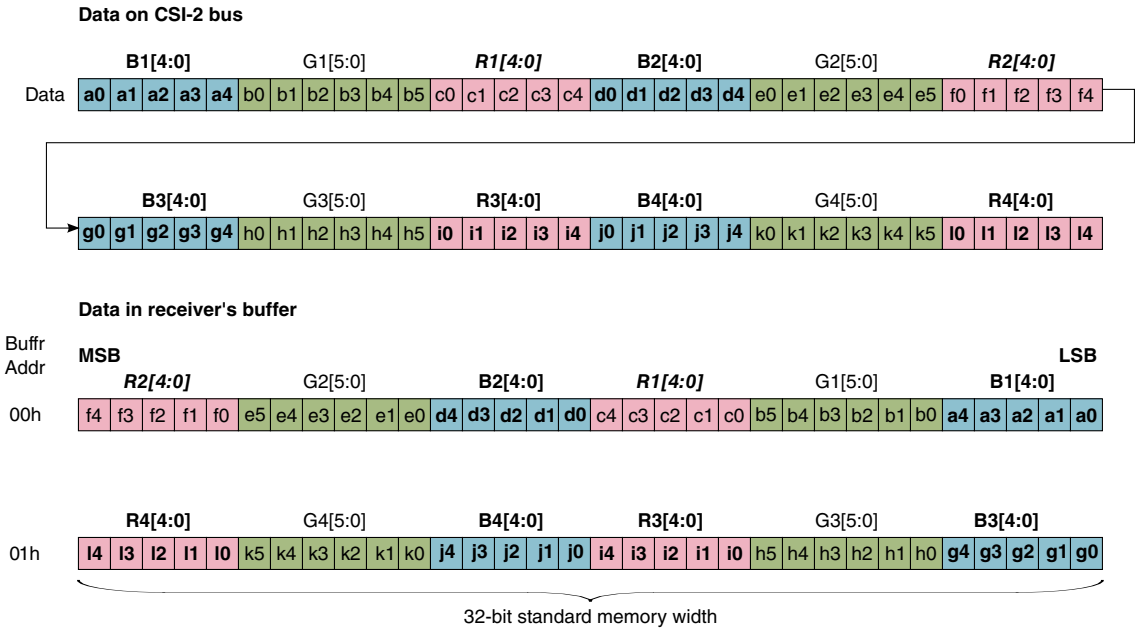

Figure 40-15. RGB565 Data Format Reception.

40.5.5 RGB555 Data Reception

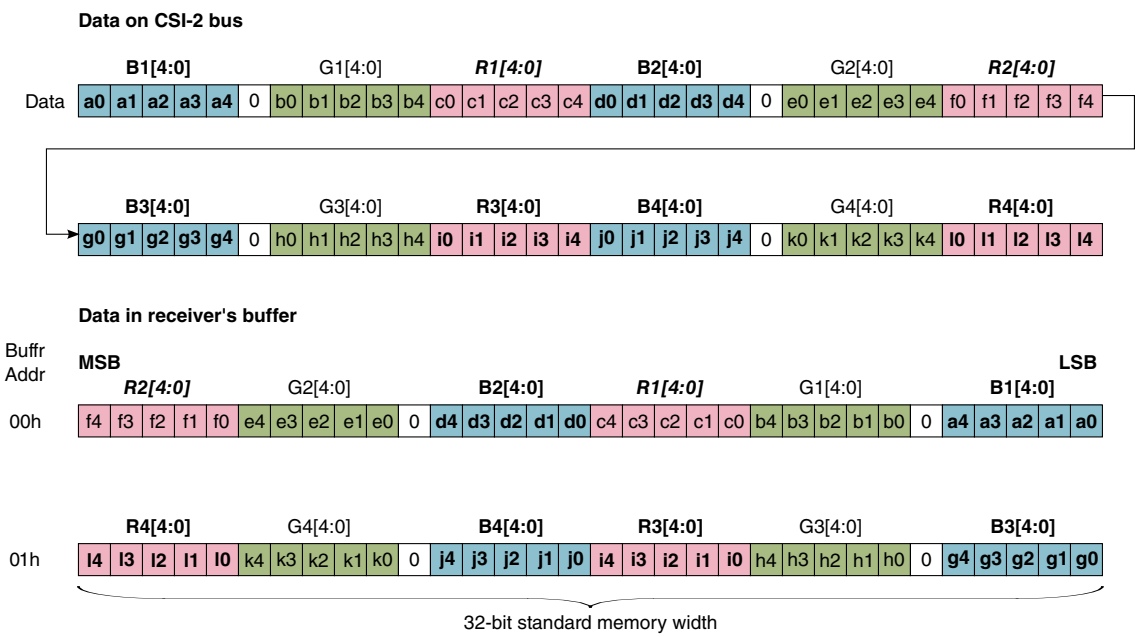

Figure 40-16. RGB555 Data Format Reception.

40.5.6 RGB444 Data Reception

The RGB444 data format byte to 32-bit memory word mapping has a special transform as shown in the following Figure:

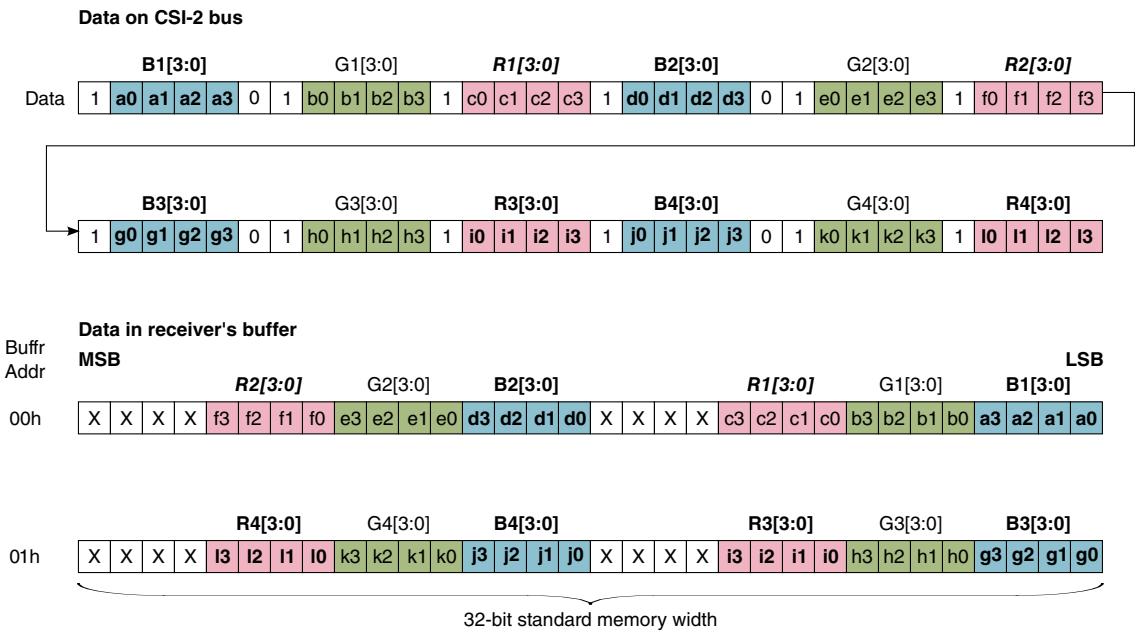

Figure 40-17. RGB444 Data Format Reception.

40.5.7 YUV422 8-bit Data Reception

The YUV422 8-bit data format the byte to 32-bit memory word mapping does not follow the generic CSI-2 rule.

For YUV422 8-bit data format the first byte of payload data transmitted maps the most significant byte of the 32-bit memory word and the fourth byte of payload data transmitted maps to the least significant byte of the 32-bit memory word.

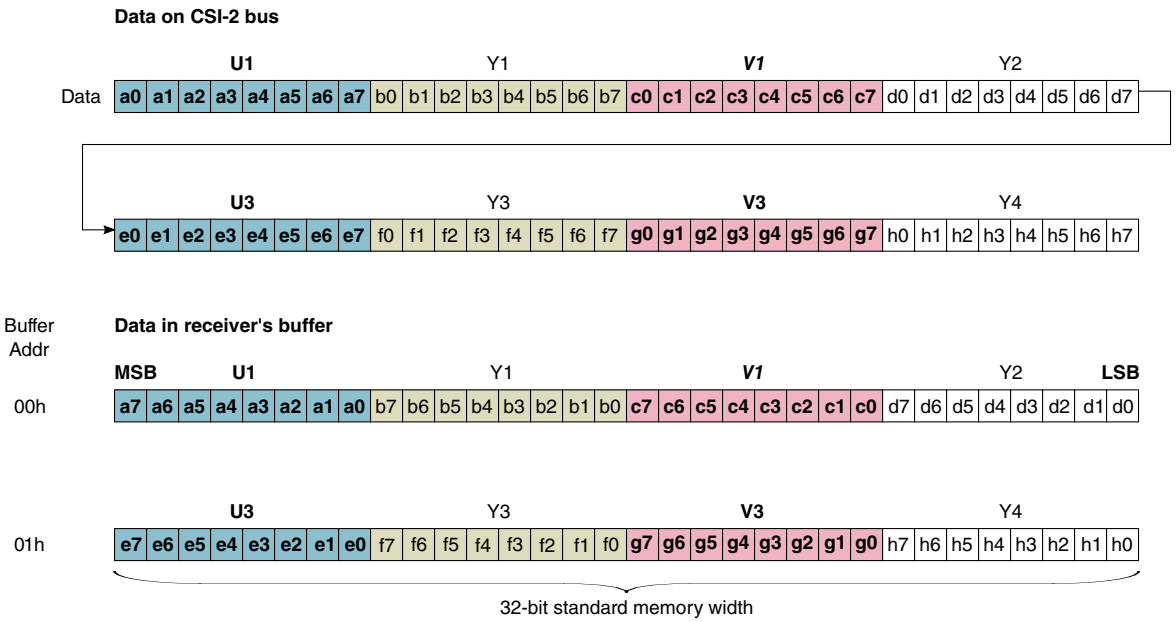

Figure 40-18. YUV422 8-bit Data Format Reception.

40.5.8 YUV422 10-bit Data Reception

The YUV422 10-bit data format the byte to 32-bit memory word mapping follows the generic CSI-2 rule.

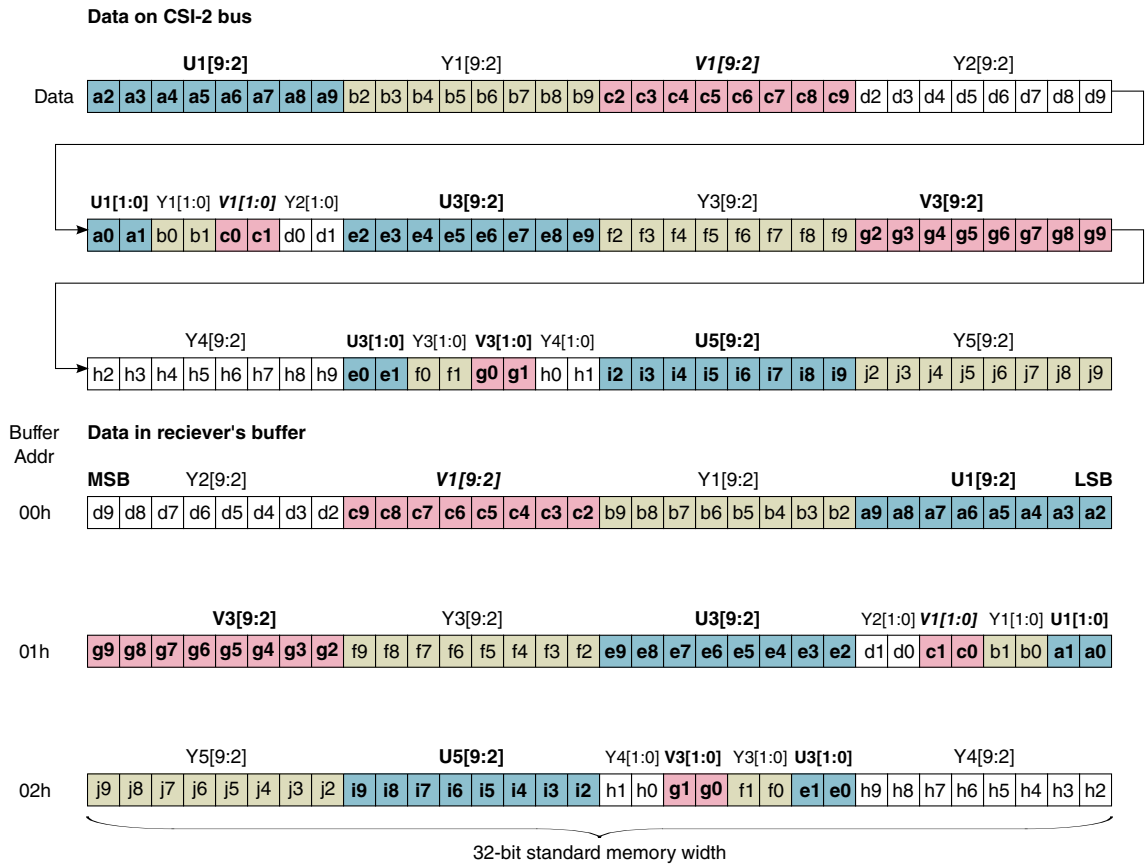

Figure 40-19. YUV422 10-bit Data Format Reception.

40.5.9 YUV420 8-bit (Legacy) Data Reception

The YUV420 8-bit (legacy) data format the byte to 32-bit memory word mapping does not follow the generic CSI-2 rule.

For YUV422 8-bit (legacy) data format the first byte of payload data transmitted maps the MS byte of the 32-bit memory word and the fourth byte of payload data transmitted maps to the LS byte of the 32-bit memory word.

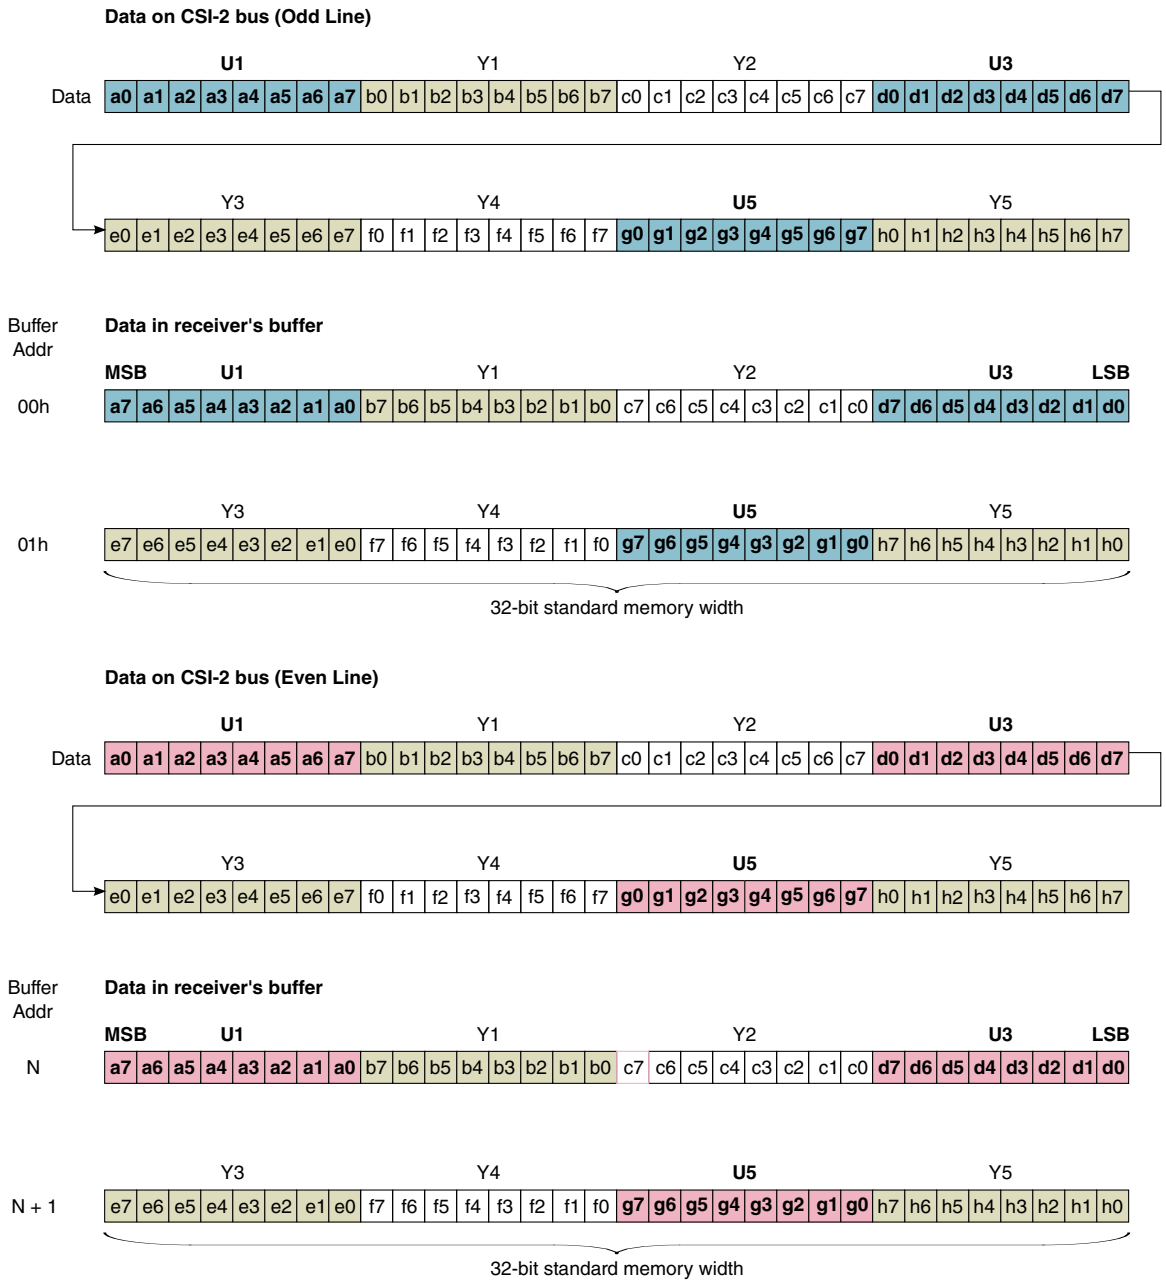

Figure 40-20. YUV420 8-bit Legacy Data Format Reception.

40.5.10 YUV420 8-bit Data Reception

The YUV420 8-bit data format the byte to 32-bit memory word mapping follows the generic CSI-2 rule.

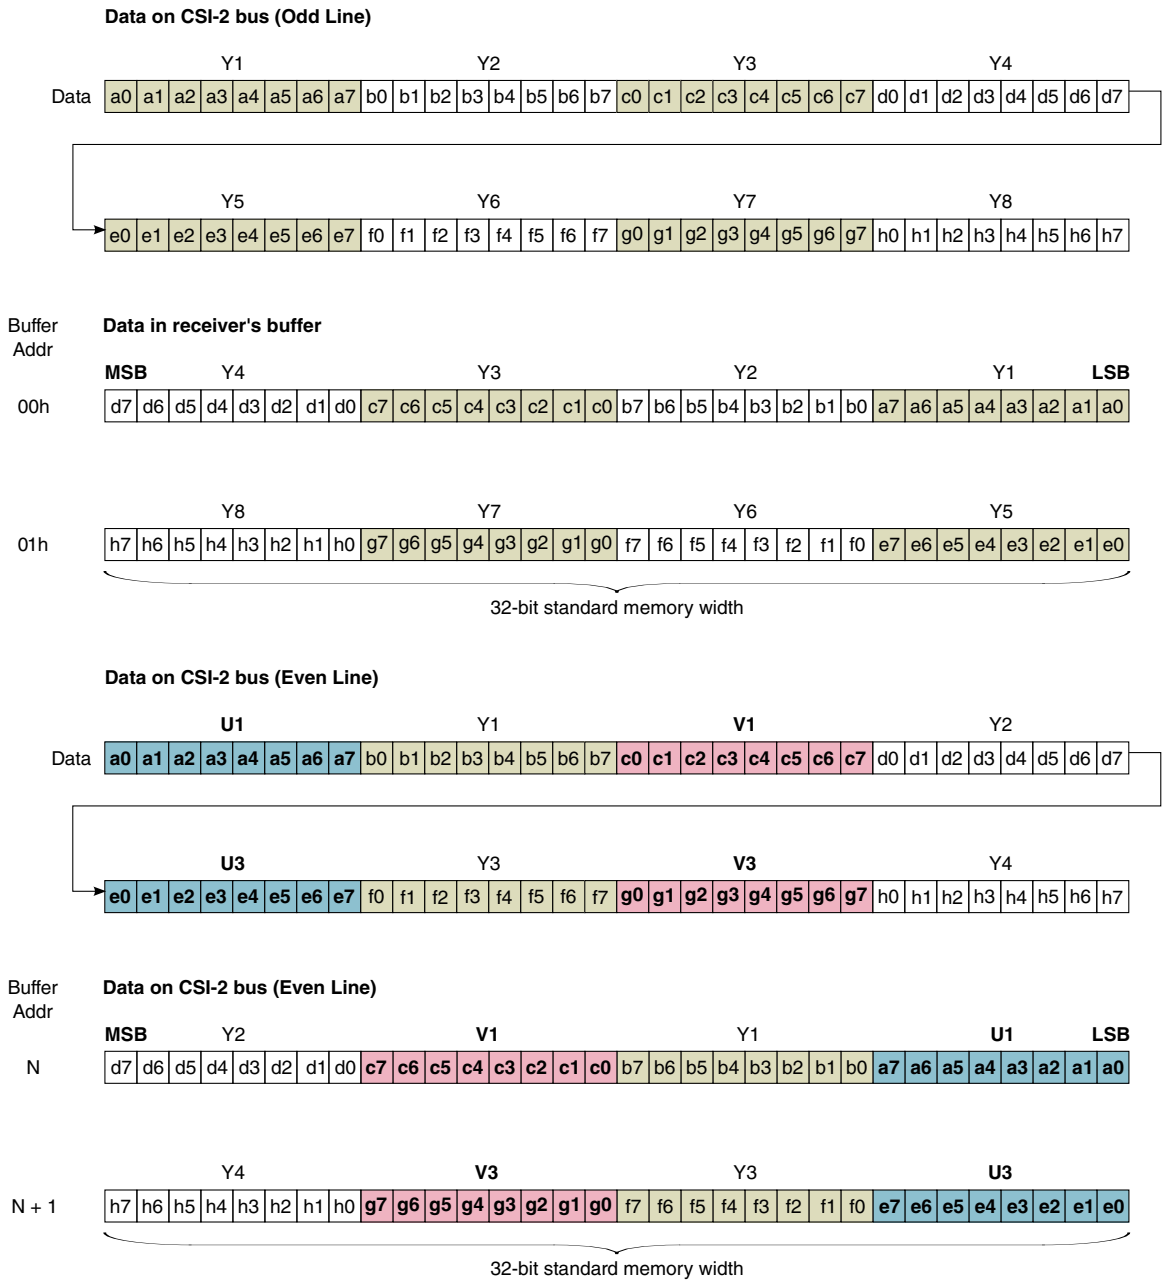

Figure 40-21. YUV420 8-bit Data Format Reception.

40.5.11 YUV420 10-bit Data Reception

The YUV420 10-bit data format the byte to 32-bit memory word mapping follows the generic CSI-2 rule.

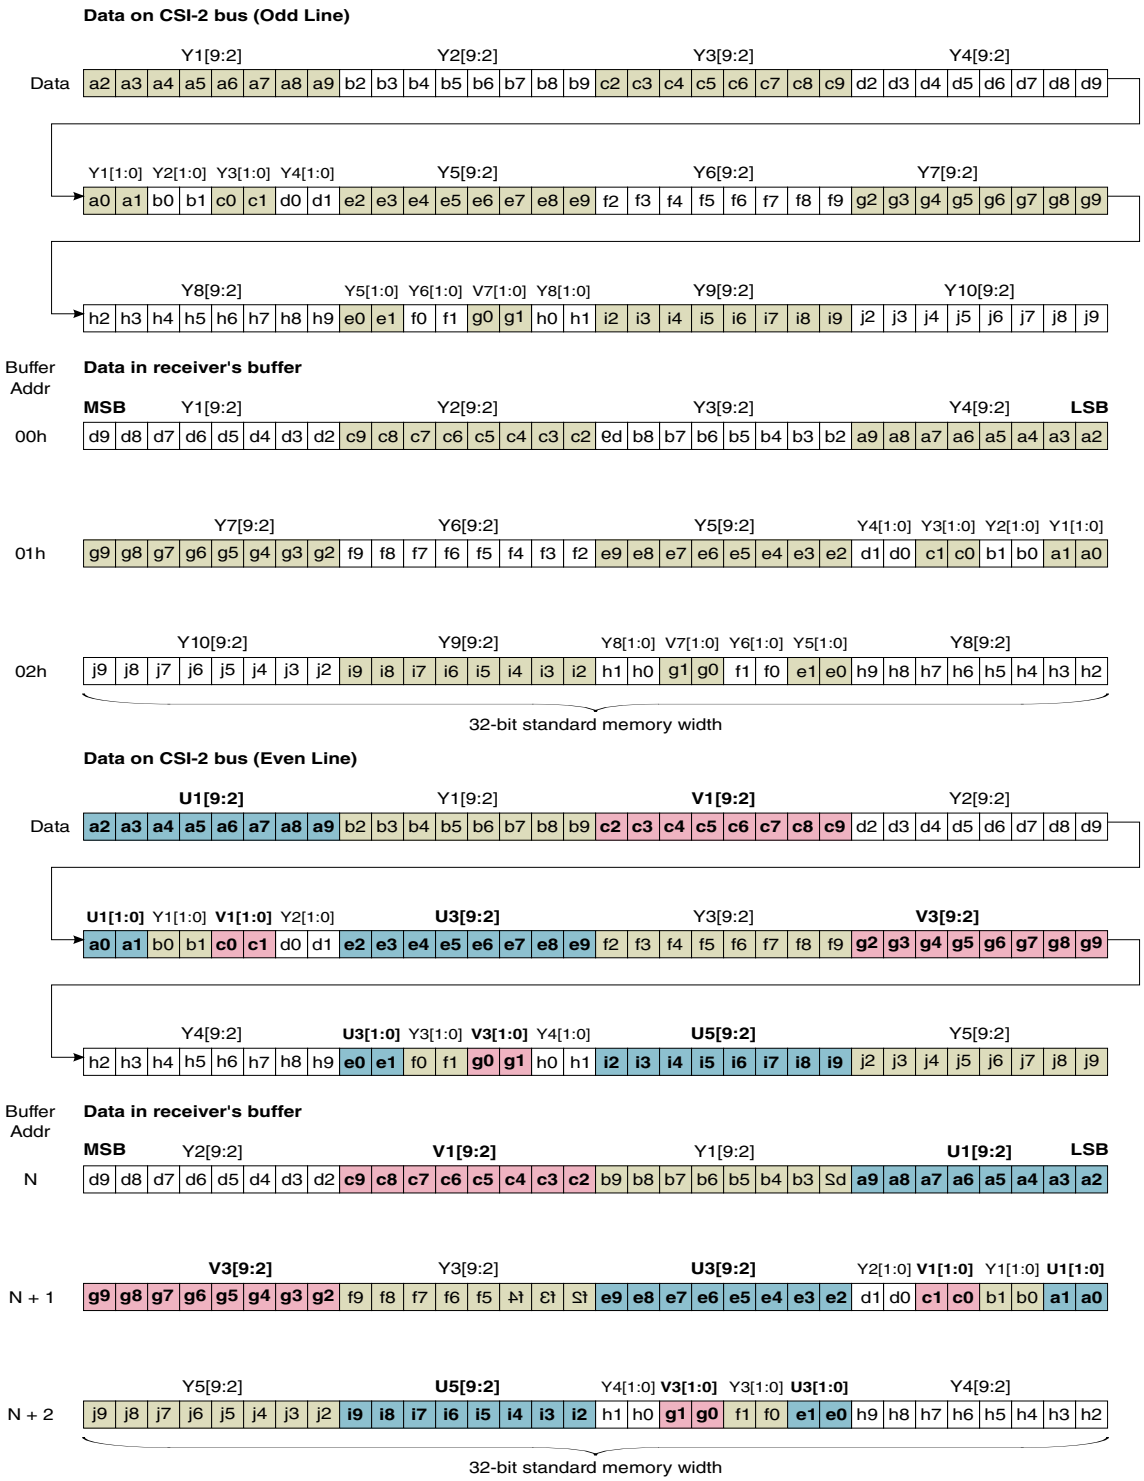

Figure 40-22. YUV420 10-bit Data Format Reception.

40.5.12 RAW6 Data Reception

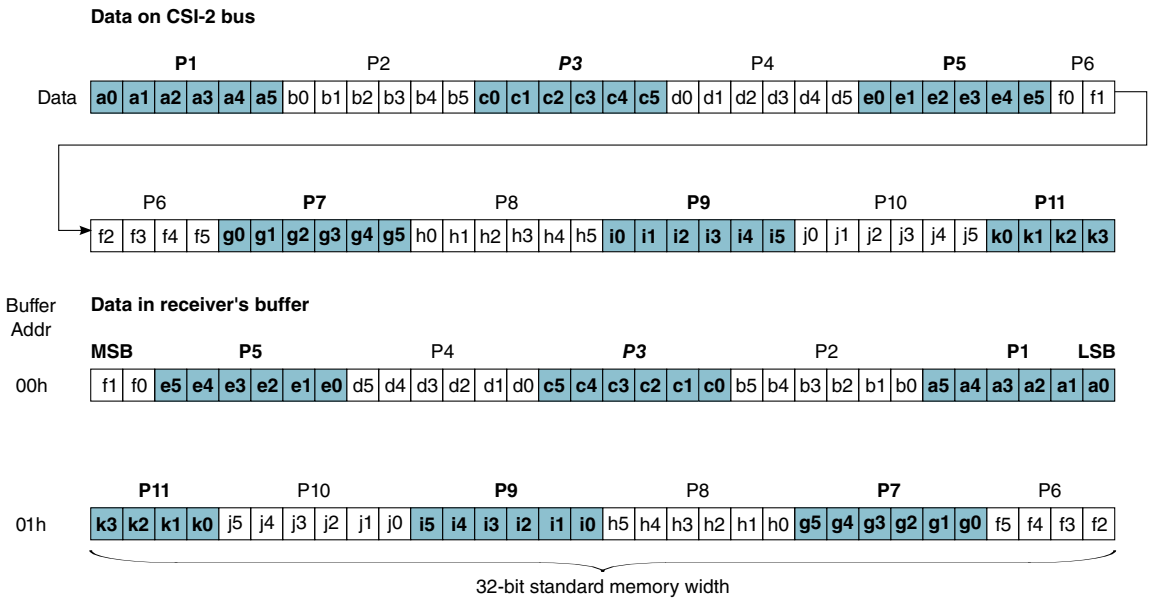

Figure 40-23. RAW6 Data Format Reception.

40.5.13 RAW7 Data Reception

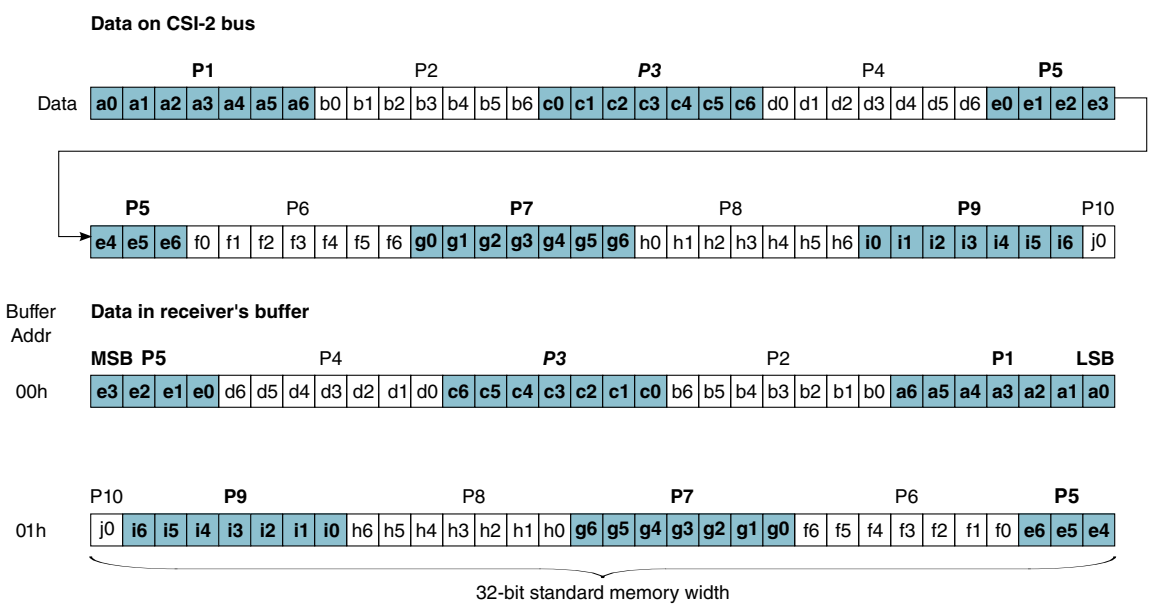

Figure 40-24. RAW7 Data Format Reception.

40.5.14 RAW8 Data Reception

The RAW8 data format the byte to 32-bit memory word mapping follows the generic CSI-2 rule.

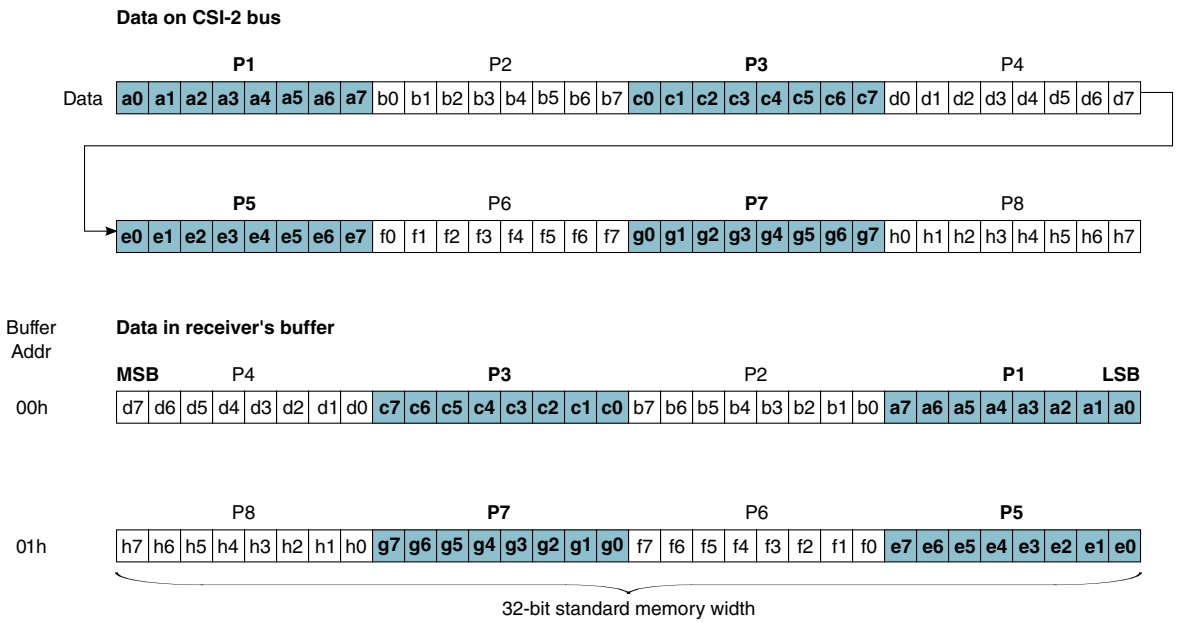

Figure 40-25. RAW8 Data Format Reception.

40.5.15 RAW10 Data Reception

The RAW10 data format the byte to 32-bit memory word mapping follows the generic CSI-2 rule.

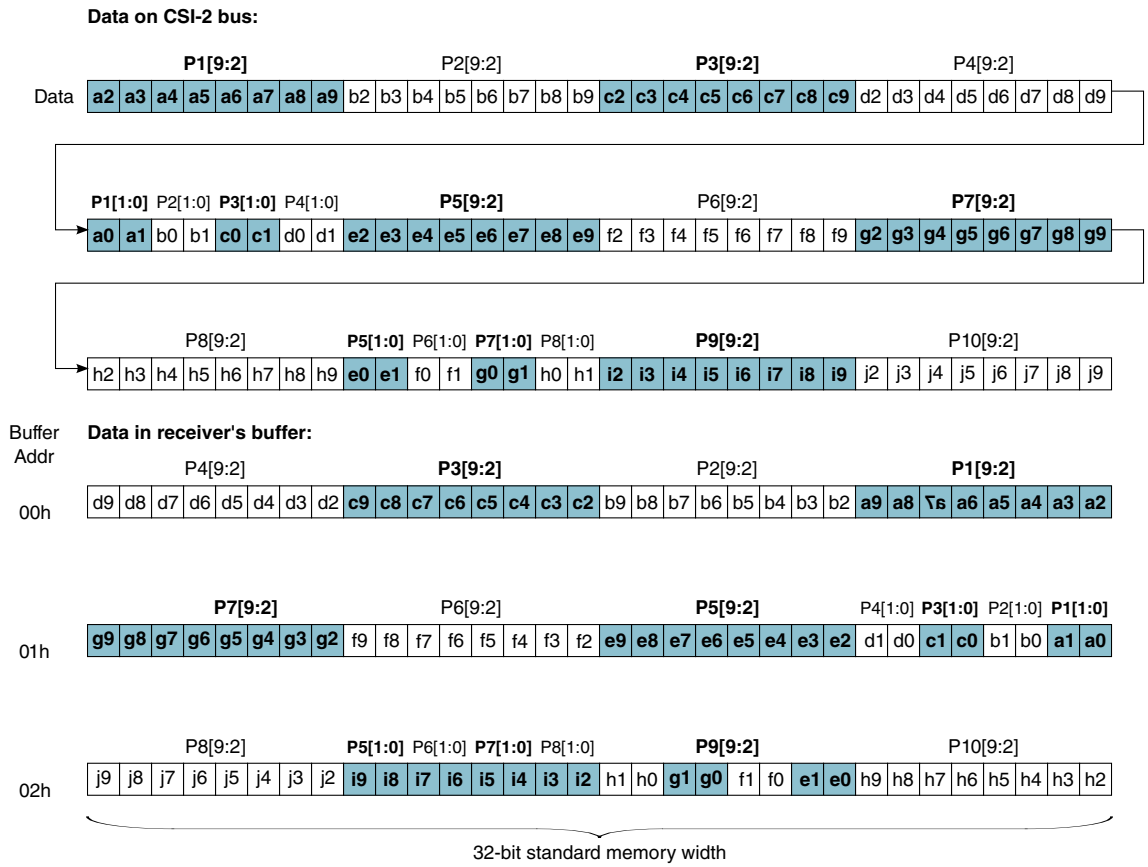

Figure 40-26. RAW10 Data Format Reception.

40.5.16 RAW12 Data Reception

The RAW12 data format the byte to 32-bit memory word mapping follows the generic CSI-2 rule.

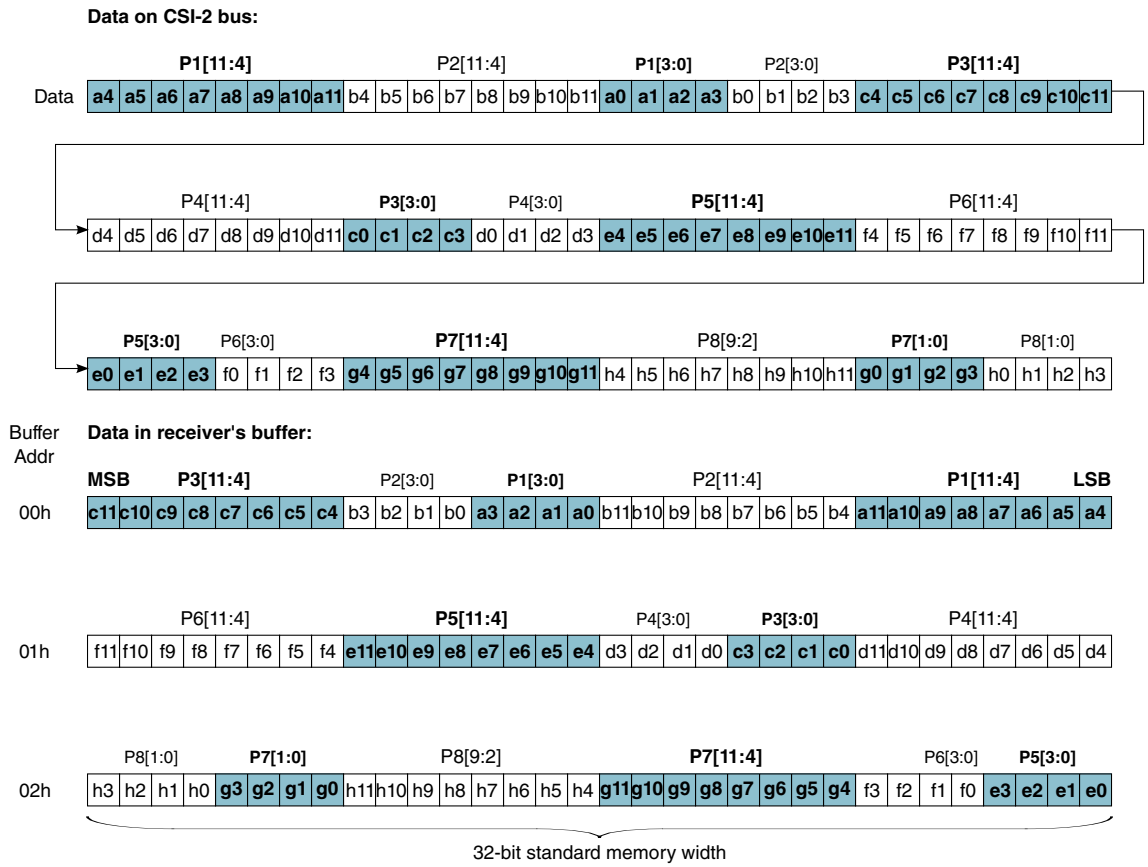

Figure 40-27. RAW12 Data Format Reception.

40.5.17 RAW14 Data Reception

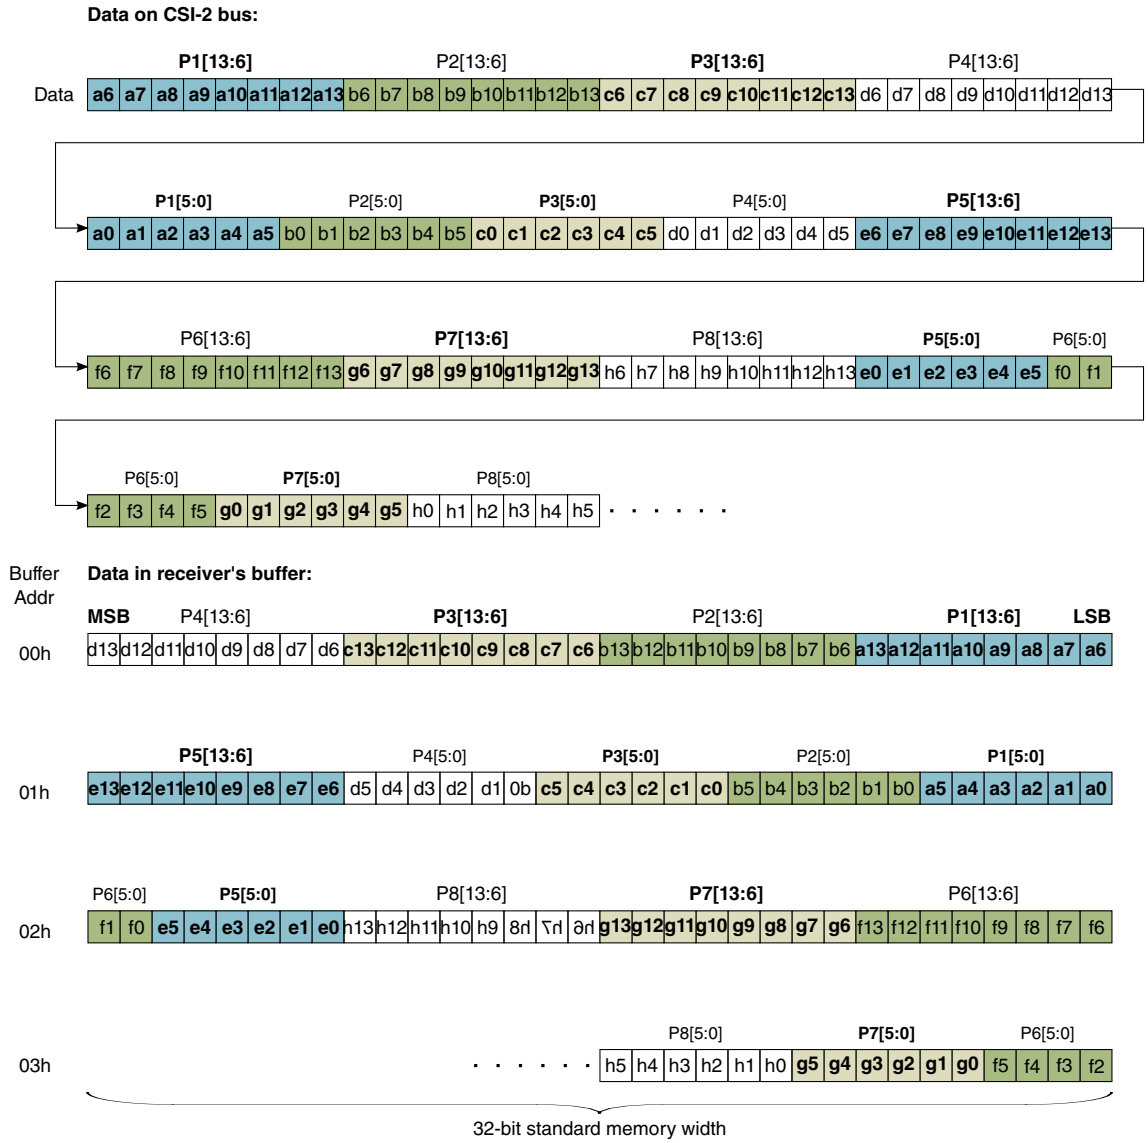

Figure 40-28. RAW 14 Data Format Reception.

Chapter 41
MIPI DSI Host Controller (MIPI_DSI)

41.1 Overview

The DSI Host Controller is a digital core that implements all protocol functions defined in the MIPI DSI Specification, providing an interface between the System and the MIPI D-PHY, and allowing communication with a MIPI DSI-compliant Display.

41.2 Features

The MIPI DSI Host Controller supports the following features:

Compliant with MIPI Alliance Specification for Display Serial Interface (DSI), Version 1.01.00 - 21 February 2008;

- Fully Compliant with MIPI Alliance Standard for Display Pixel Interface (DPI-2), Version 2.00 15 September 2005 with Pixel Data bus width up to 24bits
- Compliant with MIPI Alliance Standard for Display Bus Interface (DBI-2) Version 2.00 - 29 November 2005. Supported DBI types are:
  - Type B
  - 16bit, 9bit and 8bit Data bus width
- DBI and DPI interface can coexist but only one is operational
- Support all commands defined in MIPI Alliance Specification for Display Command Set (DCS), Version 1.02.00 - 23 July 2009

Interface with MIPI D-PHY following PHY Protocol Interface (PPI), as defined in MIPI Alliance Specification for D-PHY, Version 1.00.00 - 14 May 2009;

Supports up to 2 D-PHY Data Lanes:

- Bidirectional Communication and Escape Mode Support through Data Lane 0.
- Programmable display resolutions, from 160x120(QQVGA) to 1280x720(XVGA).
- Multiple Peripheral Support capability, configurable Virtual Channels.

- Video Mode Pixel Formats, 16bpp(RGB565), 18 bpp(RGB666) packed, 18 bpp(RGB666) loosely, 24 bpp(RGB888).
- Supports the transmission of all generic commands;
- ECC and Checksum capabilities;
- End of Transmission Packet (EoTp) support;
- Supports ultra low power mode
- Schemes for fault recovery.

41.2.1 System Overview

The DSI Host Controller is a digital core that implements all protocol functions defined in the MIPI DSI Specification, providing an interface between the System and the MIPI D-PHY, allowing the communication with a MIPI DSI compliant Display.

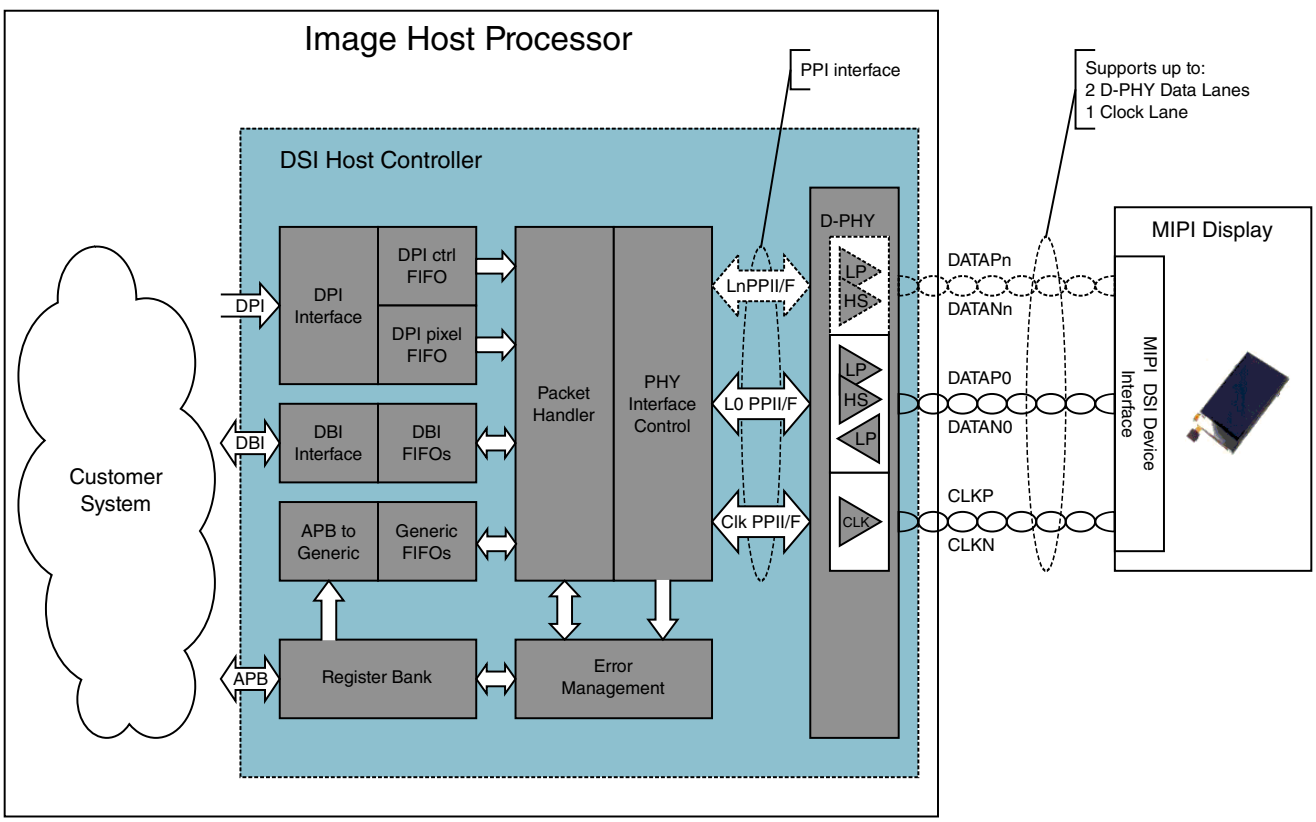

Figure 41-1. Block Diagram.

41.3 Clocks

The table found here describes the clock sources for MIPI.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 41-1. MIPI Clocks

Clock name	Clock Root	Description
ac_clk_125m	ahb_clk_root	Bus clock
pixel_clk	axi_clk_root	Pixel clock
cfg_clk	video_27m_clk_root	Configuration clock
ips_clk	ipg_clk_root	Peripheral clock
ips_clk_s	ipg_clk_root	Peripheral access clock
pll_refclk	video_27m_clk_root	Video reference clock (27MHz)

41.4 Architecture

This section describes the DSI Host Controller block interfaces, protocols, functionality, and implementation.

41.4.1 Architecture Overview

The following figure presents the overall architecture of the DSI Host Controller. The main blocks are the following:

DPI interface captures data and control signals from the DPI interface and conveys them in a FIFO for video control signals and another one for the pixel data.

DBI interface encapsulates DCS commands in DSI packets that are then conveyed into command and payload FIFOs. For commands that require a response from the device, the block uses an incoming data FIFO to acquire data from peripheral.

Register Bank is accessible through a standard AMBA-APB slave interface, providing access to the DSI Host Controller registers for configuration and control. There is also a fully programmable interrupt generator to inform the system upon certain events.

PHY Interface Control is responsible for managing the D-PHY PPI interface. It acknowledges current operation and enables LP transmission/reception or a High Speed transmission. It also performs data splitting between available D-PHY Lanes for High Speed transmission.

Packet Handler schedules activity inside the link. It performs several functions based on the interfaces that are currently operational (DPI and/or DBI) and the video transmission mode that is used (burst mode or non-burst mode with sync pulses or sync events). It

builds long or short packet generating correspondent ECC and CRC codes. This block also handles packet reception: Validates packet header by checking ECC, performs header correction for single bit erros and notifies and abort reception for multiple header errors. Depending on the packet type, generic read response or DCS command, route the output data to the respective port (generic or DBI)

APB to Generic block bridges APB operations into FIFOs holding the Generic commands. The block interfaces with 3 FIFOS, a command FIFO, a write payload FIFO and a read payload FIFO.

Error Management notifies and monitors error conditions on the DSI link. It controls timers used to determine if a time out condition occurred and triggers interruption for errors.

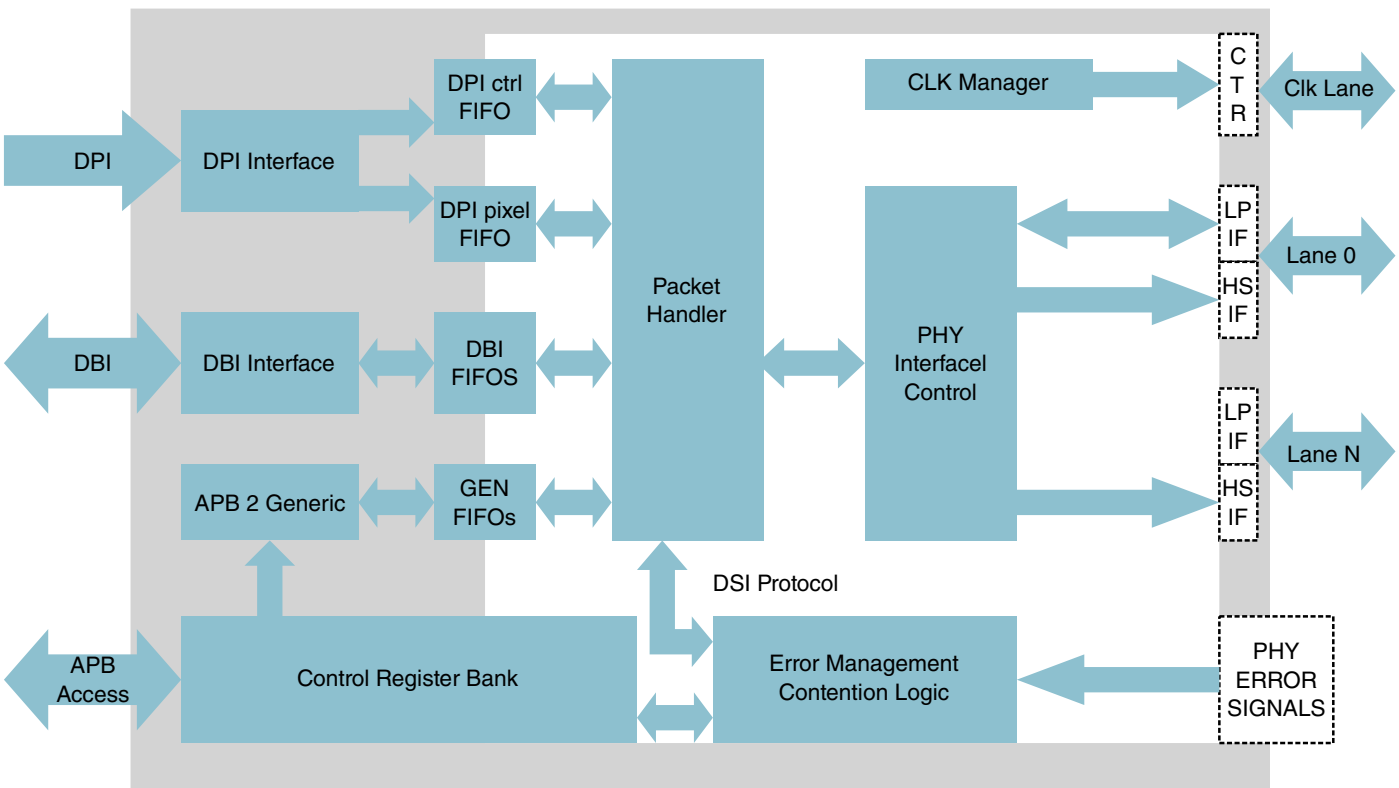

Figure 41-2. DSI Host Controller Architecture

41.4.2 DBI-2 interface

The DBI-2 interface encapsulates DCS commands in DSI packets to be transmitted through the D-PHY link. Some commands require a response from the device and the interface provides read data from the device/peripheral.

The support DBI types is Type B interface

The selection type maps the related pins on the DSI core pinout. DBI interface used RGB additive color mixing method and the pixel data format is selected on register DBI_CFG register. The field **in_dbi_conf** defines the input pixel data format and field **out_dbi_conf** defines the output pixel data that is determined by the display device. This interface needs to be associated with a particular DSI Virtual Channel that is programmed on field **dbi_vid**.

The following figures show how the pixel to byte conversion is done for each mode. All the diagrams are representing the case were the interface is working as type B.

The DBI interface type B signals list .

DBICSX: Chip select, it is low active .

DBIRDX: Read signal, the read data should be captured at the DBIRDX rising edge .

DBIWRX: Write signal, the write data will be switch at DBIWRX falling edge.

DBIDATIN[15:0]: Write data

DBIDCX: Data commnad select, Data is indicated when high and command is indicated when low .

DBITE: Tearing effect.

DBI interface receives commands and decodes information for the command packetizing format. Depending on the command type, DSI core output the related DSI packet type (DCS short write packet; DCS read packet or DCS long write). If the DCS commands have variable size this needs to be configured on the DBI_CMDSIZE register. The following table presents DCS packet types:

Table 41-2. DSI packet types for DCS commands

DCS command	Command ID	DCS parameter	DSI packet type
enter_idle_mode	0x39h	0	6'h05
enter_invert_mode	0x21h	0	6'h05
enter_normal_mode	0x13h	0	6'h05
enter_partial_mode	0x12h	0	6'h05

get_display_mode	0x0Dh	1(read)	6'h06
get_green_channel	0x07h	1(read)	6'h06
get_pixel_format	0x0Ch	1(read)	6'h06
get_power_mode	0x0Ah	1(read)	6'h06
get_red_channel	0x06h	1(read)	6'h06

Table continues on the next page...

Table 41-2. DSI packet types for DCS commands (continued)

DCS command	Command ID	DCS parameter	DSI packet type
get_scan_line	0x45h	2(read)	6'h06
get_signal_mode	0x0Eh	1(read)	6'h06
read_DDB_continue	0xA8h	n(read)	6'h06
read_DDB_start	0xA1h	n(read)	6'h06
read_memory_continue	0x3Eh	n(read)	6'h06
read_memory_start	0x2Eh	n(read)	6'h06

All packets that have 1 or 0 parameters index to the command are considered short packet and all other shall be considered long packets.

There are several register fields to configure DBI input pixel data and DBI pixel data retrieval. It is required to have prior knowledge of display supported feature to avoid incorrectly core configuration. Some guidelines are presented below to clarify how core uses the configuration for its operation.

Field **in_dbi_conf** in register DBI_CFG configures the color depth and the pixel format used by the input interface. Field **out_dbi_conf** configures the colour depth and the pixels format used by the output interface. Here the colour depth is directly related with formats supported by the peripheral. If the peripheral returns pixel data with a specific colour depth this colour depth should be consistent with the register configuration. If this is not respected, the byte to pixel converter will use an incorrect pixel mapping and it will corrupt output data.

Field **out_dbi_conf** should not be programmed for a higher number of interface pins than **in_dbi_conf**. As an example an incorrect pin configuration happens if **in_dbi_conf** defines 9 bit interface and **out_dbi_conf** defines 16 bit since pins 16 to 10 will not be available.

Field **lut_size_conf** configures the size of the DCS write_LUT command; this command will program the peripheral's colour space conversion table. This register is directly related with the capabilities of the peripheral. If the peripheral supports a colour depth of 16/18/24 bits per pixel it is expected that this register is configured for 48/128/192 bytes respectively. These coefficients should be loaded to the peripheral before normal operation of pixel data transmission is started. The DCS specification only refers to the conversion of formats equal or above 12bpp. This means that any format outside this scope might not be convertible to a higher colour depth mode by the peripheral. Taking this in consideration, when **in_dbi_conf** selects a colour depth below 12bpp, the **out_dbi_conf** should be configured such that colour depth has not a higher value. As an example, if **in_dbi_conf** is configured for 8bits/8bpp interface and **out_dbi_conf** is configured for 8bits/12bpp, this results in an incorrect configuration because the DCS

specification does not contemplates conversions from 8bpp to 12bpp. This configuration is possible inside the core but might lead into incorrect results. Nevertheless it is left for the system to configure these registers according with the desired operation.

For Read back commands the DBI specification states that the reading process does not use any acknowledge mechanism to know that the requested data is ready. There are mechanisms for the system to get this information by polling the Command Status Register CMD_PKT_STATUS. This register, besides other information, contains the status on the DBI read back payload FIFO and also contains a special busy flag **dbi_rd_cmd_busy** that can be used to understand if the read command is complete. By using the DBI read back FIFO status bits that report if the FIFO is full or empty the processor can read these bits to understand if it can read another byte/sample from the interface (probing the empty flag) or when it should stop reading bytes/samples from the interface. In addition, the Read Command Busy flag is asserted when a read command is issued by the interface and cleared once the reading process ends and the read data is fully stored inside the read back FIFO. The system needs to issue the read command and then periodically probe this status bit to acknowledge if the read back operation is complete. Once this information is available the system can assume that the entire data is stored inside the read back FIFO and the interface can deliver all the desired data.

41.4.3 DPI-2 Interface

The DPI-2 interface captures data and control signals and conveys them to FIFO interfaces that will transmit them to the DSI link. Two different streams of data are presented at the interface: video control signals and pixel data. Depending on the interface color coding, the pixel data is handled differently throughout the dpipixdata bus.

Interface pixel color coding is presented in the table below.

Table 41-3. DPI interface pixel color coding mapping.

Signal Line	16-bit			18-bit		24-bit
	Config1	Config2	Config3	Config1	Config2	
D23	Not used	Not used	Not used	Not used	Not used	R7

D1	B1	B1	B0	B1	B1	B1
D0	B0	B0	Not used	B0	B0	B0

The DPI interface can be configured to increase flexibility and promote correct usage of this interface for several systems. These configuration options are described below:

- Polarity control. All the control signals are programmable to change polarity according to system requirements.
- After core reset, DPI waits for the first VSYNC active transition to start signals sampling, including pixel data and preventing image transmission in the middle of a frame.
- If interface pixel color coding is 18 bits and the 18 bit loosely packet stream is enabled, the number of lines programmed in the pixels per lines configuration is a multiple of four. This means that in this mode the 2 LSB in the configuration will be always inferred as zero. Specification states that in this mode the pixel line size should be a multiple of 4.
- To avoid pixel underflows and overflows the configured number of pixel will originate the respective memory spaces. This will happen even if the dpidataen pin is active during more or less time than necessary.
- In order to keep the memory organized in respect to the packet scheduling the number of pixels per packet parameter will be used to separate the memory space of different video packets.

For the **dpishutd** and **dpicolorm** sampling and transmission the DPI video signalling must be active. This means that if video signals like VSYNC and HSYNC are not being actively generated the DPI commands these are not transmitted through the DSI link. The

DSI commands packets have the highest priority in the class of Non Video packets. Because of such constraint and in order for commands to be correctly transmitted, the first VSYNC active pulse needs to happen for the commands sampling and transmission. When shutting down the display, it is necessary for DPI video to keep active for one frame after the command being issued. This guarantees that the commands are correctly transmitted before actually disabling the Video generation in the DPI interface.

41.4.4 Error control and timeout timers

The DSI host controller implements a set of timers and conditions to notify errors.

The core has a set of registers to control the timers that will be used to determine if a time out has occurred. It also contains a set of interruption status registers that are cleared upon read operation. These registers also trigger an interruption pin that can be used by the system to act upon an error within the DSI connection.

41.4.5 Timeout timers

Bit **to_hs_tx** on register ERROR_ST1 is set when a High Speed Transmission Time Out occurs rising an interrupt pin.

The time out is configured in **hstx_to_cnt** field of register TO_CNT_CFG. A 16 bit counter measures the time when High Speed is active. If that counter reaches the value defined by register **hstx_to_cnt**, bit **to_hs_tx** is asserted.

Bit to_lp_rx on register ERROR_ST1 is set signaling contention detection when a Low Power Reception Time Out occurs rising an interrupt pin. The time out is configured in **lprx_to_cnt** field of register TO_CNT_CFG. A 16 bit counter measures the time when Low Power reception is active. If that counter reaches the value defined by register **lprx_to_cnt**,bit **to_lp_rx** is asserted.

Time units for this 16bit counters are configured in cycles defined in **TO_CLK_DIVISION** field in register CLKMGR_CFG. The value written to **TO_CLK_DIVISION** defines the time unit for the Time out limits using Lane byte clock as input. This mechanism increases the range to define these limits.

41.4.6 Error control

Two registers ERROR_ST0 and ERROR_ST1 are associated with error condition reporting. This resister can trigger interrupt pins to inform the system about the occurrence of errors.

The coreConsultant GUI allows different interrupt pin configuration that can support:

- No interrupt pin on DSI core for notification of error although system can check for error by reading error status registers ERROR_ST0 and ERROR_ST0.
- DSI core has one interrupt pin interrupt that is set High when an error occurs either in register ERROR_ST1 or ERROR_ST2.
- DSI core has 2 interrupts associated with each error status register. Pins interrupt0 and interrupt1 are respectively associated with ERROR_ST1 and ERROR_ST2. This mechanism allows faster association of interrupts with the status register that generated the error.

The triggering of the interrupt pins, when defined, can be masked by programming the mask registers ERROR_MSK0 and ERROR_MSK1. When any bit of this registers is set to 1 it will inhibit the interrupt for that specific error. Nevertheless the error bit will always be set on the respective ERROR_ST register. Registers ERROR_ST1 and ERROR_ST2 are always cleared when read.

The figure below illustrates the location of some of the errors.

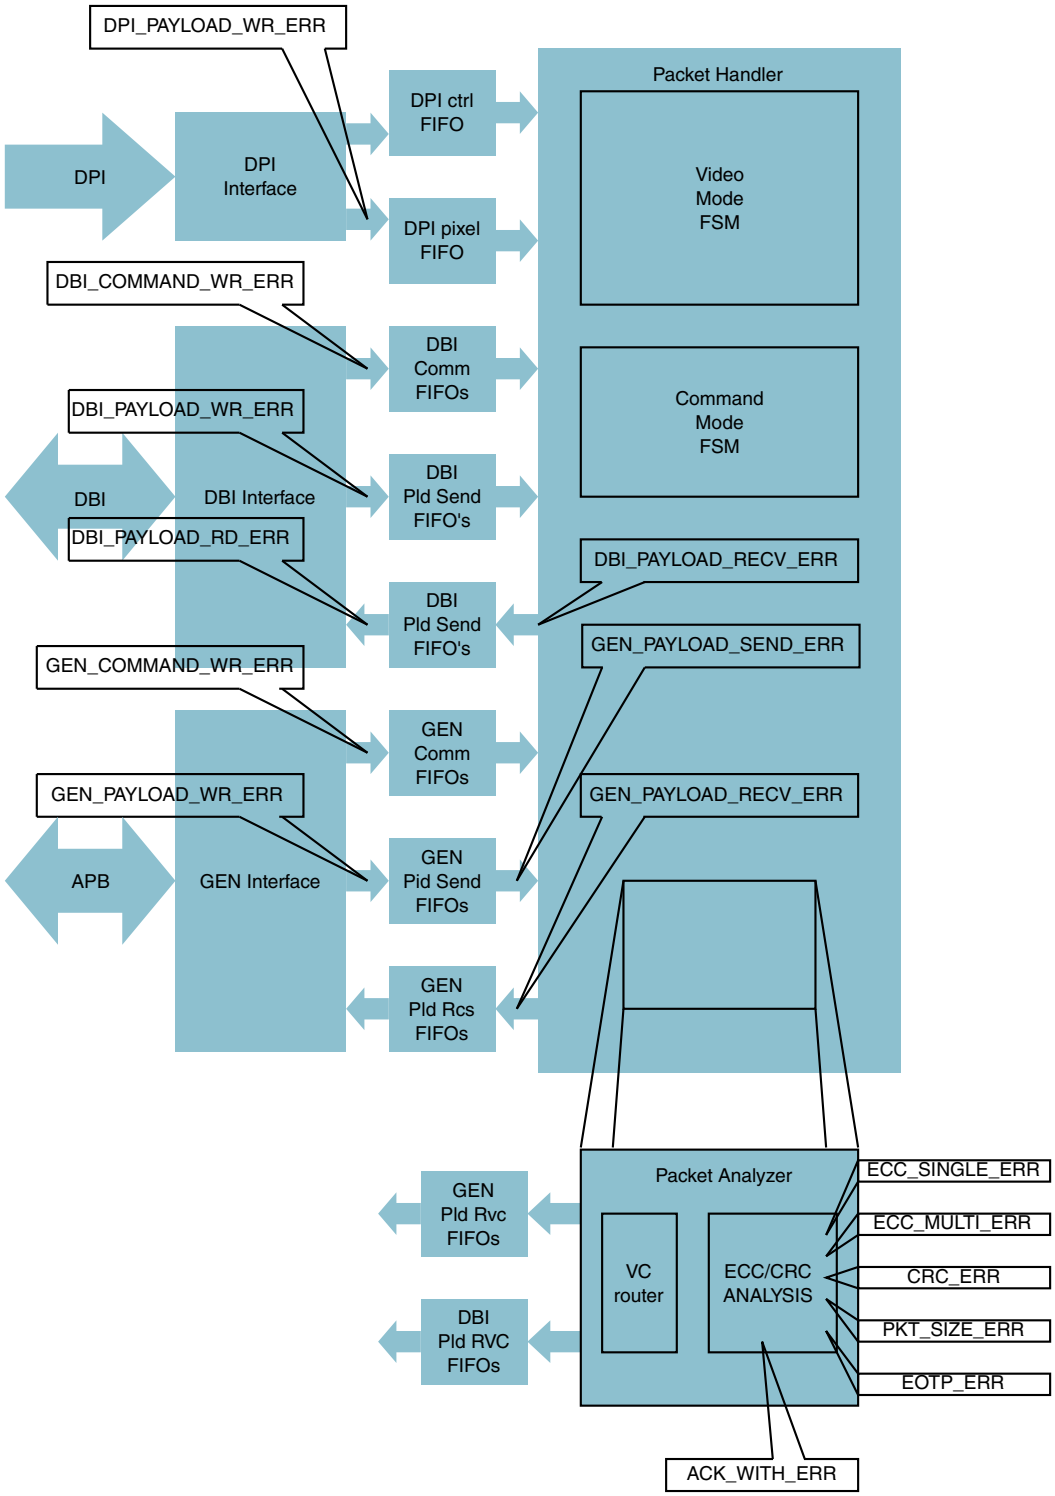

Figure 41-16. Error sources diagram

41.4.7 Generic packets

DSI host Core support generic packets transmission and reception as described in the DSI-2 specification. These packets are channeled through the APB register bank.

Register GEN_PLD_DATA is used to write payload of generic packets and when read it returns the payload of a read back operation. Register GEN_HDR contains the generic packet header type and header data. Writing to this register triggers the transmission of the packet implying that for long generic packets data needs to be written in advance on register GEN_PLD_DATA.

The valid packets available to be transmitted through the Generic interface are:

Table 41-4. Generic interface available packets

Generic Write Short Packet 0 Parameters	Generic Write Short Packet 1 Parameters	Generic Write Short Packet 2 Parameters	Generic Read Short Packet 0 Parameters
Generic Read Short Packet 1 Parameters	Generic Read Short Packet 2 Parameters	Maximum Read Packet Configuration	Generic Long Write Packet
DCS Write Short Packet 0 Parameters	DCS Write Short Packet 1 Parameters	DCS Read Short Packet 0 Parameters	DCS Write Long Packet

A set of bits in register CMD_PKT_STATUS report the status of the FIFOs associated with generic packet support.

Generic packets are always transported using one of the DSI transmission modes: Video Mode or Command Mode. If none of these modes are selected the packets will not be transmitted through the link and the related FIFOs will eventually get overflowed.

If system does not requires Generic packets support this functionality can be disabled in coreConsultant GUI and the interfaces with the 2-port RAMs that buffer command, payload and read data are removed.

41.4.8 Signals

A Clock Lane and a Data Lane (Lane0) with TX HS features are always required. Data Lanes can be up to a maximum of 2.

Table 41-5. D-PHY external interface

Pin Name	Width	Direction	Description
DPHY Supply			
AVDD	1	Input	D-PHY Analog power supply.
VDD	1	Input	D-PHY Digital power supply.
AVDDREF	1	Input	D-PHY Analog supply for reference generator.

DATAN1	1	Input	D-PHY Negative D-Phy differential data line transceiver output, Lane 1

41.5 Programming

41.5.1 DSI and D-PHY initialization sequence

This chapter describes the procedure for DSI and D-PHY initialization. This process is based on APB register interface access.

- By default register PHY_RSTZ is activating the PHY resets **physhutdownz**, **phyrstz** and disabling **enableclk** and register PHY_TEST_CTRL0 is by default asserting the **testclr** pin. All the PHY reset pins are being activated by default.
- Configure Register PHY_IF_CFG with correct the number of lanes to be used by the controller.
- Configure the TX_ESC clock frequency to a frequency lower than 20MHz that is the maximum allowed frequency for D-PHY ESCAPE mode. This is done by writing in Register CLKMGR_CFG, field TX_ESC_CLK_DIVISION.
  TX_ESC_CLK_DIVISION divides Byte Clock and generates a TX_ESC clock for the D-PHY. (Note: Byte clock is limited to 125MHz (1GHz/8bits) and by writing TX_ESC_CLK_DIVISION=0x07 TX_ESC clock will always be lower than 20MHz)
- Configure the DPHY PLL clock frequency through the TEST Interface to operate at 1GHz, assuming that the REF_CLK is provided with a frequency of 27MHz

- Write @ PHY_TST_CTRL0 - 32'h00000000 this disables the **testclr** pin enabling the interface to write new values to the DPHY internal registers.
- Write @ PHY_TST_CTRL1 - 32'h00010044 this enables the **testen** pin bit 17 of this Core register and configures the **testdatain** to 8'h44. This operation initiate the configuration process of the test code number 0x44.
- Write @ PHY_TEST_CTRL0 - 32'h0000002 followed by a new write to PHY_TEST_CTRL0 - 32'h00000000. This operation toggles the **testclk** (bit 2) and the **testdin** will be sampled on the falling edge of **testclk** latching a new test code.
- Write @ PHY_TEST_CTRL1 - 32'h00000074 disabling the testen pin and configuring **testdatain** to 8'h74. This operation prepares the interface to load in test code 0x44 the 0x74 value.
- Write @ PHY_TEST_CTRL0 - 32'h00000002 followed by a new write to PHY_TEST_CTRL0 - 32'h00000000. This operation toggles the **testclk** and the **testdin** will be sampled on the rising edge of **testclk** latching a new content data to the configured test code.

- Write @ PHY_RSTZ - 32'h00000007. This operation asserts **physhutdownz**, **phyrstz** and **enableclk** releasing the PHY from power down. The PHY will startup the PLL locking procedure to 1GHz operation.
- Read @ PHY_STATUS - 32'hxxxxxxx1, until bit 0 **phylock** is detected at 1 signaling that PLL is locked and that a stable byte clock is being provided to the DSI host controller.
- Read @ PHY_STATUS - 32'hxxxxx1x1, until bit 2 **phystopstateclklane** is read '1' identifying that Clock Lane is in Stop State. Clock lane need to be in Stop state so that the D-PHY can switch to other operational states such as the High Speed mode.
- Write register PHY_IF_CTRL bit 0 to generate High Speed clock (**txrequestHSclk**).
- Only after: 1) PLL locked and 2) Clock lane in Stop-State; the PHY will drive the correct LP sequence to configure the receiver end for HS.
- D-PHY starts transmitting HS clock on the Clock Lane.

41.6 MIPI_DSI Memory Map/Register Definition

MIPI_DSI memory map

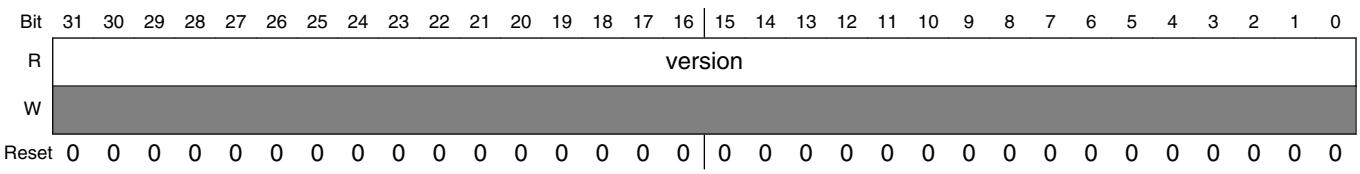
41.6.1 Version of the DSI host ctrl (MIPI_DSI_VERSION)

Size: 32 bits

Offset: 0x0

Memory Access: R

Address: 21E_0000h base + 0h offset = 21E_0000h



MIPI_DSI_VERSION field descriptions

Field	Description
version	Version of the DSI host controller

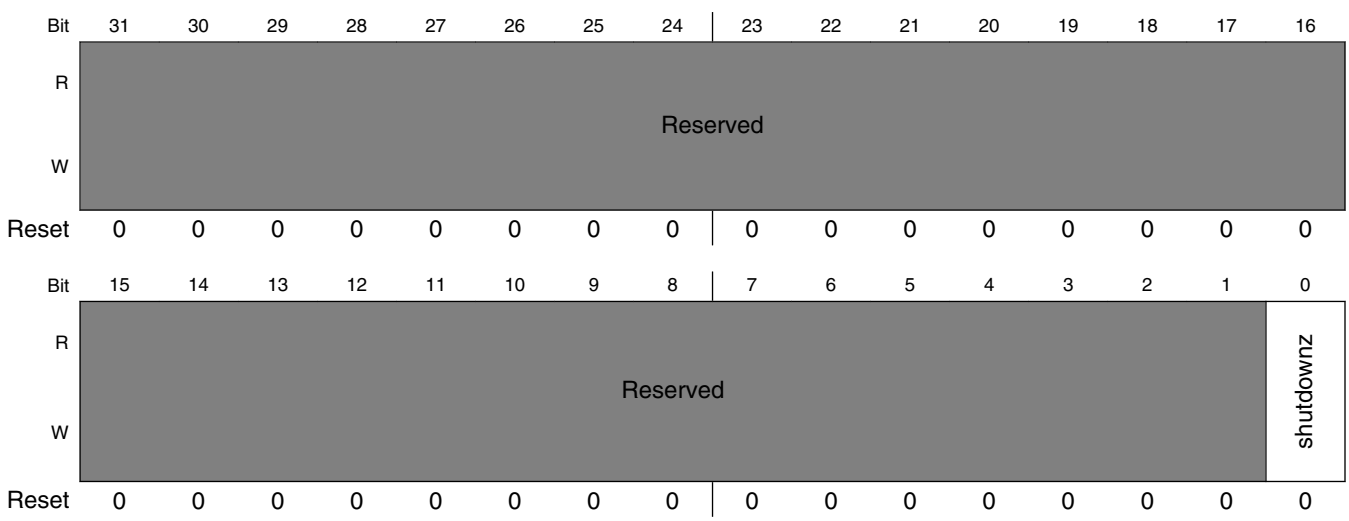
41.6.2 Core power up (MIPI_DSI_PWR_UP)

Size: 32 bits

Offset: 0x4

Memory Access: R/W

Address: 21E_0000h base + 4h offset = 21E_0004h



MIPI_DSI_PWR_UP field descriptions

Field	Description
31–1 -	This field is reserved. Reserved
0 shutdownz	Core power up 0 reset; 1 power up)

41.6.3 Number of active data lanes (MIPI_DSI_CLKMGR_CFG)

Size: 32 bits

Offset: 0x8

Memory Access: R/W

Address: 21E_0000h base + 8h offset = 21E_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_DSI_CLKMGR_CFG field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 TO_CLK_ DIVIDSION	Division factor for Time Out clock used as timing unit in the configuration of HS to LP and LP to HS transition error.
TX_ESC_CLK_ DIVIDSION	Division factor for TX ESCAPE clock source (lanebyteclk pin), values 0 and 1 stop TX_ESC clock generation.

41.6.4 DPI interface configuration (MIPI_DSI_DPI_CFG)

Size: 32 bits

Offset: 0xc

Memory Access: R/W

Address: 21E_0000h base + Ch offset = 21E_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved					en18_loosely	colorm_active_low	shutd_active_low	hsync_active_low	vsync_active_low	dataen_active_low	dpi_color_coding			dpi_vid	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_DSI_DPI_CFG field descriptions

Field	Description
31–11 -	This field is reserved. Reserved
10 en18_loosely	Enable 18 loosely packet pixel stream.
9 colorm_active_low	Set to configure Color Mode pin (dpicolcorm) as Active low
8 shutd_active_low	Set to configure Shut Down pin (dpishutdn) as Active low
7 hsync_active_low	Set to configure Horizontal Synchronism pin (dpihsync) as Active low
6 vsync_active_low	Set to configure Vertical Synchronism pin (dpivsync) as Active low
5 dataen_active_low	Set to configure Data enable pin (dpidaten) as Active low
4–2 dpi_color_coding	DPI color coding. 0 16bit config1 1 16bit config2; 2 16bit config3; 3 18bit config1; 4 18bit config2; 5 to 7 24 bit.
dpi_vid	Configures the DPI Virtual Channel ID that will be indexed to the Video mode packets.

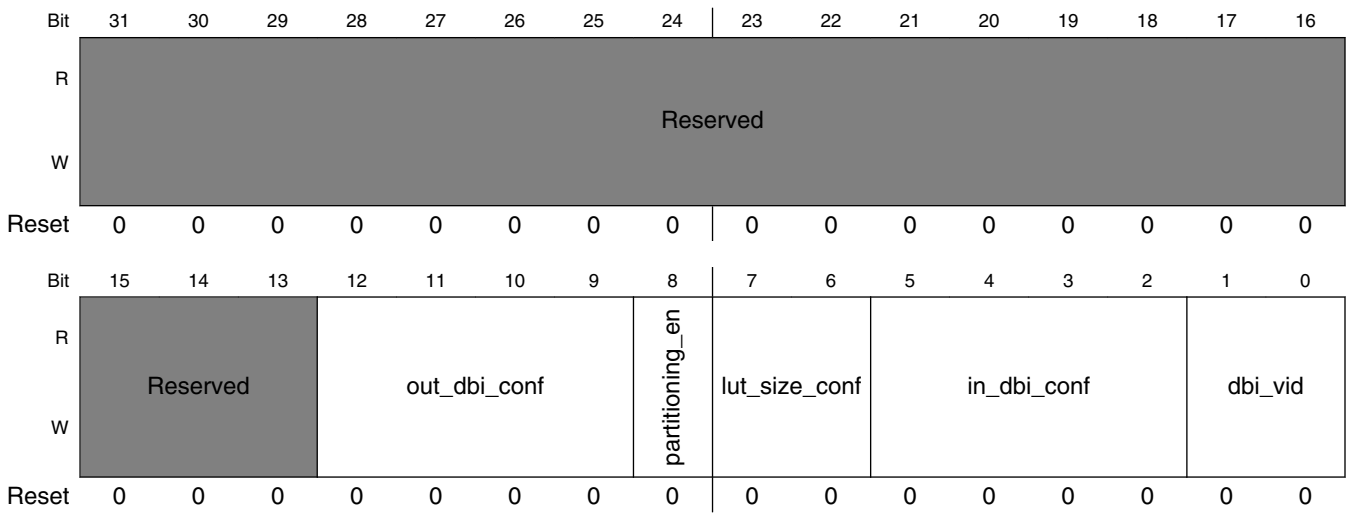
41.6.5 DBI interface configuration (MIPI_DSI_DBI_CFG)

Size: 32 bits

Offset: 0x10

Memory Access: R/W

Address: 21E_0000h base + 10h offset = 21E_0010h



MIPI_DSI_DBI_CFG field descriptions

Field	Description
31–13 -	This field is reserved. Reserved
12–9 out_dbi_conf	Configures the DBI output pixel data configuration; 0 8bit 8bpp; 1 8bit 12bpp; 2 8bit 16bpp; 3 8bit 18bpp; 4 8bit 24bpp; 5 9bit 18bpp; 6 16bit 8bpp; 7 16bit 12bpp; 8 16bit 16bpp; 9 16bit 18bpp, option1; 10 16bit 18bpp, option2; 11 16bit 24bpp, option1; 12 16bit 24bpp, option2
8 partitioning_en	Enables write memory continue through input command (system needs to ensure correct partitioning of Long Write commands)

Table continues on the next page...

MIPI_DSI_DBI_CFG field descriptions (continued)

Field	Description
7–6 lut_size_conf	Configures the size used to transport Write Lut commands; 0 16-bit color display; 1 18-bit color display; 2 24-bit color display; 3 16-bit color display
5–2 in_dbi_conf	Configures DBI input pixel data configuration; 0 8bit 8bpp; 1 8bit 12bpp; 2 8bit 16bpp; 3 8bit 18bpp; 4 8bit 24bpp; 5 9bit 18bpp; 6 16bit 8bpp; 7 16bit 12bpp; 8 16bit 16bpp; 9 16bit 18bpp, option1; 10 16bit 18bpp, option2; 11 16bit 24bpp, option1; 12 16bit 24bpp, option2
dbi_vid	Configures the DBI Virtual Channel ID that will be indexed to the DCS packets.

41.6.6 DBI command size configuration (MIPI_DSI_DBIS_CMDSIZE)

Size: 32 bits

Offset: 0x14

Memory Access: R/W

Address: 21E_0000h base + 14h offset = 21E_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	allowed_cmd_size																wr_cmd_size															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_DSI_DBIS_CMDSIZE field descriptions

Field	Description
31–16 allowed_cmd_size	Configures the maximum allowed size of a DCS write memory command. This register is used to partition a write memory command into several write memory continues. It is only used if bit 'partitioning_en' is disabled. Size of DSI packet payload is the actual payload size minus 1 since the DCS command is in the DSI packet payload.

Table continues on the next page...

MIPI_DSI_DBIS_CMDSIZE field descriptions (continued)

Field	Description
wr_cmd_size	Configures the size of the DCS write memory commands. Size of DSI packet payload is the actual payload size minus 1 since the DCS command is in the DSI packet payload.

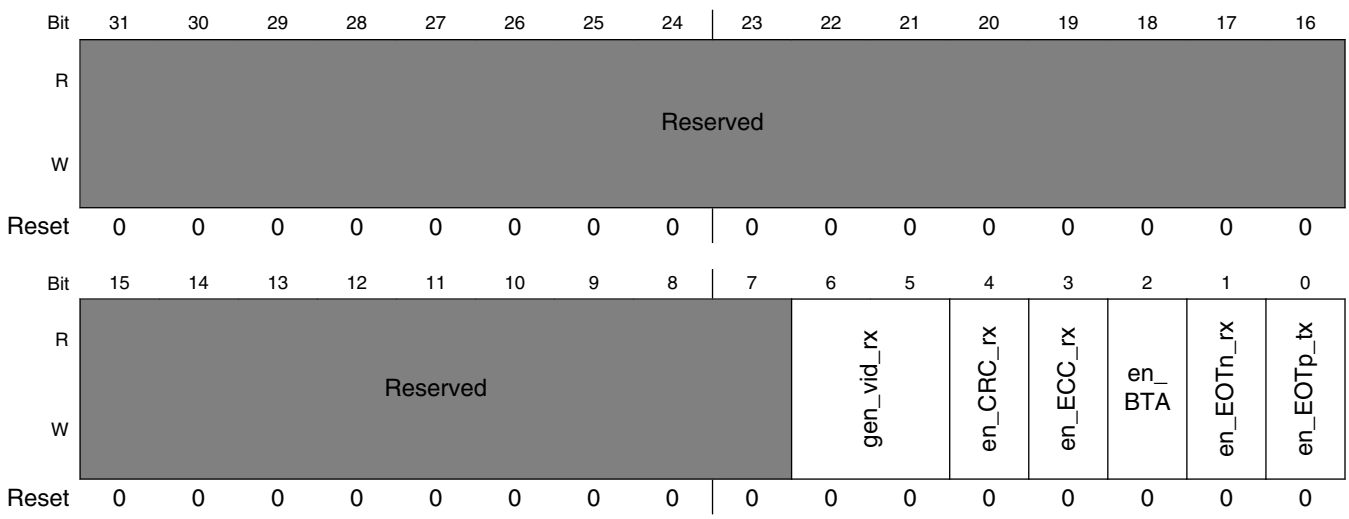
41.6.7 Packet handler configuration (MIPI_DSI_PCKHDL_CFG)

Size: 32 bits

Offset: 0x18

Memory Access: R/W

Address: 21E_0000h base + 18h offset = 21E_0018h



MIPI_DSI_PCKHDL_CFG field descriptions

Field	Description
31–7 -	This field is reserved. Reserved
6–5 gen_vid_rx	Generic interface read-back Virtual Channel identification
4 en_CRC_rx	Enables CRC reception and error reporting
3 en_ECC_rx	Enables ECC reception, error correction and reporting
2 en_BTA	Enables Bus Turn-Around request
1 en_EOTn_rx	Enables EOTp reception
0 en_EOTp_tx	Enables EOTp transmission

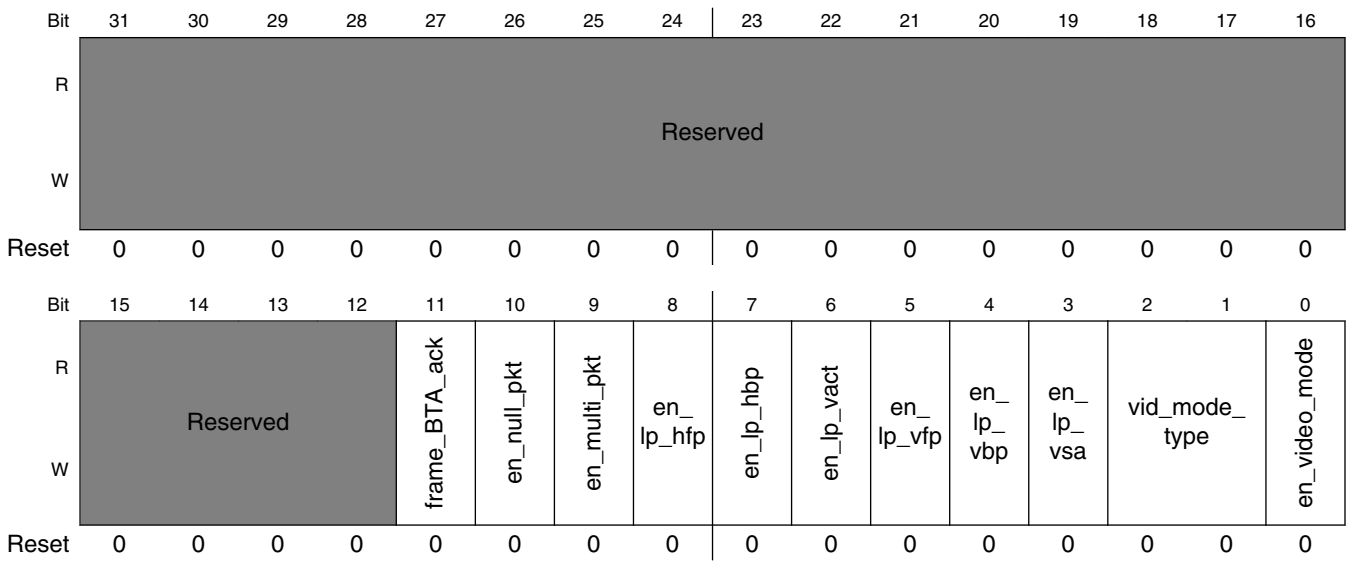
41.6.8 Video Mode Configuration (MIPI_DSI_VID_MODE_CFG)

Size: 32 bits

Offset: 0x1c

Memory Access: R/W

Address: 21E_0000h base + 1Ch offset = 21E_001Ch



MIPI_DSI_VID_MODE_CFG field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11 frame_BTA_ack	Enables the request for an acknowledge response at the end of a frame
10 en_null_pkt	Enables the tranmission of null packets in the HACT period
9 en_multi_pkt	Enables the tranmission of multi video packets in the HACT period
8 en_lp_hfp	Enables return to Low Power inside HFP period when timing allows
7 en_lp_hbp	Enables return to Low Power inside HBP period when timing allows
6 en_lp_vact	Enables return to Low Power inside VACT period when timing allows
5 en_lp_vfp	Enables return to Low Power inside VFP period when timing allows
4 en_lp_vbp	Enables return to Low Power inside VBP period when timing allows

Table continues on the next page...

MIPI_DSI_VID_MODE_CFG field descriptions (continued)

Field	Description
3 en_lp_vsa	Enables return to Low Power inside VSA period when timing allows
2–1 vid_mode_type	Selects video mode transmission type. 0: Non-burst with Sync pulses; 1: Non-burst with Sync events; 2-3: Burst with Sync pulses.
0 en_video_mode	Enables DPI Video mode transmission

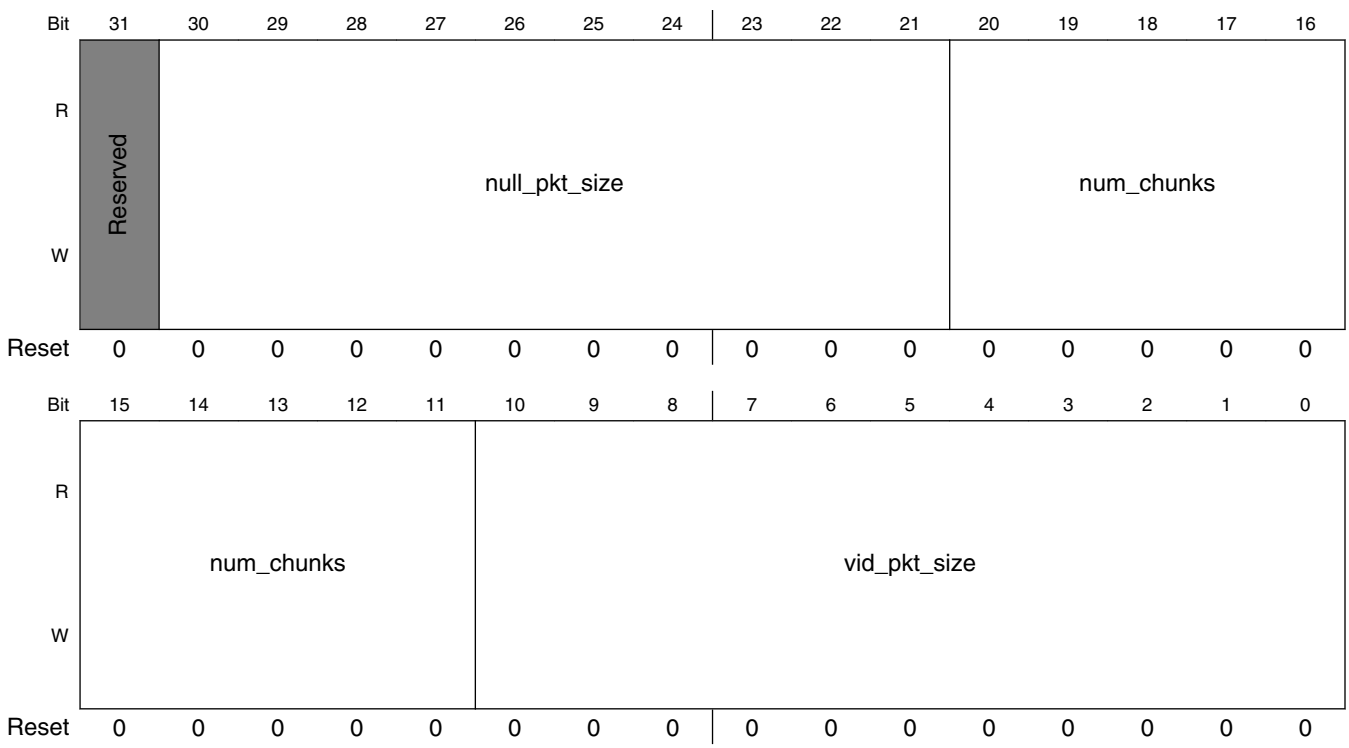
41.6.9 Video packet configuration (MIPI_DSI_VID_PKT_CFG)

Size: 32 bits

Offset: 0x20

Memory Access: R/W

Address: 21E_0000h base + 20h offset = 21E_0020h



MIPI_DSI_VID_PKT_CFG field descriptions

Field	Description
31 -	This field is reserved. Reserved

Table continues on the next page...

MIPI_DSI_VID_PKT_CFG field descriptions (continued)

Field	Description
30–21 null_pkt_size	Configures the number of bytes in a null packet
20–11 num_chunks	Configures the number of chunks to be transmitted during a Line period. (A chunk is a video packet or a null packet)
vid_pkt_size	Configures the number of pixel on a single video packet. (If using 18 bit mode and not enabling loosely packet stream this value must be a multiple of 4)

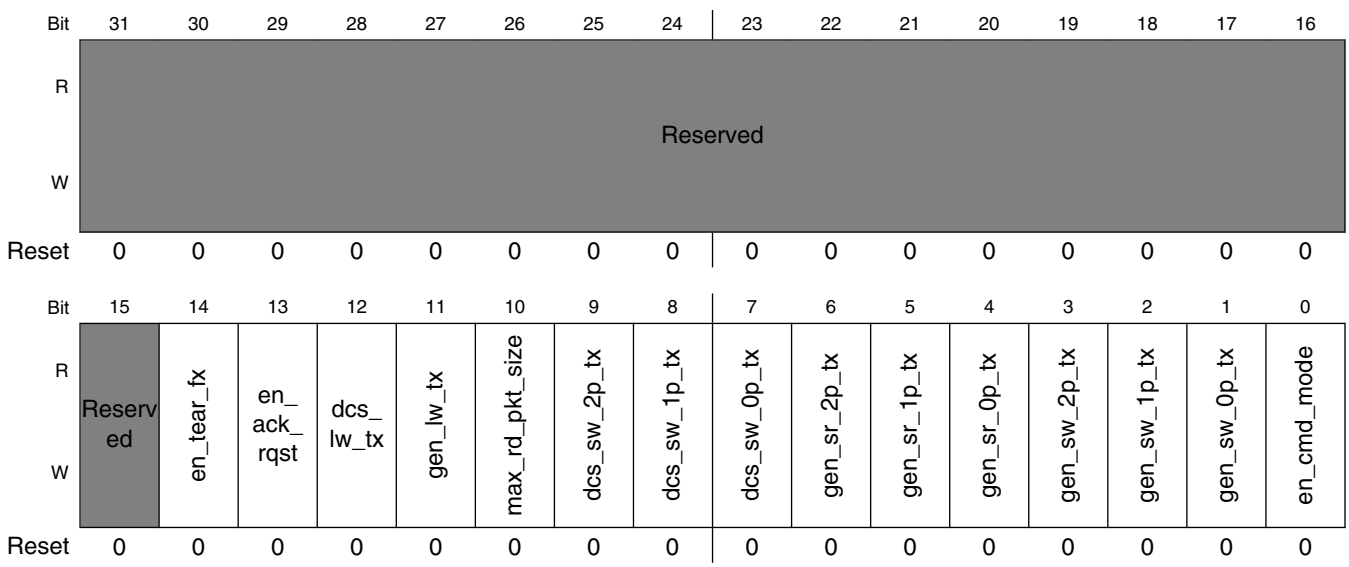
41.6.10 Command mode configuration (MIPI_DSI_CMD_MODE_CFG)

Size: 32 bits

Offset: 0x24

Memory Access: R/W

Address: 21E_0000h base + 24h offset = 21E_0024h



MIPI_DSI_CMD_MODE_CFG field descriptions

Field	Description
31–15 -	This field is reserved. Reserved
14 en_tear_fx	Enables the tearing effect acknowledge request
13 en_ack_rqst	Enables the acknowledge request after each packet transmission

Table continues on the next page...

MIPI_DSI_CMD_MODE_CFG field descriptions (continued)

Field	Description
12 dcs_lw_tx	Configures the DCS Long Write Packet command transmission type. 0 High Speed; 1 Low Power
11 gen_lw_tx	Configures the Generic Long Write Packet command transmission type. 0 High Speed; 1 Low Power
10 max_rd_pkt_size	Configures the Maximum Read Packet Size command transmission type. 0 High Speed; 1 Low Power
9 dcs_sw_2p_tx	Configures the DCS Short Write Packet with 2 Parameters command transmission type. 0 High Speed; 1 Low Power
8 dcs_sw_1p_tx	Configures the DCS Short Write Packet with 1 Parameters command transmission type. 0 High Speed; 1 Low Power
7 dcs_sw_0p_tx	Configures the DCS Short Write Packet with 0 Parameters command transmission type. 0 High Speed; 1 Low Power
6 gen_sr_2p_tx	Configures the Generic Short Read Packet with 2 Parameters command transmission type. 0 High Speed; 1 Low Power
5 gen_sr_1p_tx	Configures the Generic Short Read Packet with 1 Parameters command transmission type. 0 High Speed; 1 Low Power
4 gen_sr_0p_tx	Configures the Generic Short Read Packet with 0 Parameters command transmission type. 0 High Speed; 1 Low Power
3 gen_sw_2p_tx	Configures the Generic Short Write Packet with 2 Parameters command transmission type. 0 High Speed; 1 Low Power
2 gen_sw_1p_tx	Configures the Generic Short Write Packet with 1 Parameters command transmission type. 0 High Speed; 1 Low Power
1 gen_sw_0p_tx	Configures the Generic Short Write Packet with 0 Parameters command transmission type. 0 High Speed; 1 Low Power

Table continues on the next page...

MIPI_DSI_CMD_MODE_CFG field descriptions (continued)

Field	Description
0 en_cmd_mode	Enables the Command Mode Protocol for transmissions.

41.6.11 Line timer configuration (MIPI_DSI_TMR_LINE_CFG)

Size: 32 bits

Offset: 0x28

Memory Access: R/W

Address: 21E_0000h base + 28h offset = 21E_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MIPI_DSI_VTIMING_CFG field descriptions

Field	Description
31–27 -	This field is reserved. Reserved
26–16 v_active_lines	Configures the Vertical Active period measured in horizontal lines
15–10 vfp_lines	Configures the Vertical Front Porch period measured in horizontal lines
9–4 vbp_lines	Configures the Vertical Back Porch period measured in horizontal lines
vsa_lines	Configures the Vertical Synchronism Active period measured in horizontal lines

41.6.13 D-PHY timing configuration (MIPI_DSI_PHY_TMR_CFG)

Size: 32 bits

Offset: 0x30

Memory Access: R/W

Address: 21E_0000h base + 30h offset = 21E_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_DSI_PHY_TMR_CFG field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–20 phy_hs2lp_time	Configures the maximum time that the PHY takes to go from High Speed to Low Power transmission measured in lane byte clock cycles
19–12 phy_lp2hs_time	Configures the maximum time that the PHY takes to go from Low Power to High Speed transmission measured in lane byte clock cycles
bta_time	Configures the maximum time required to perform the Bus Turn Around operation measured in lane byte clock cycles

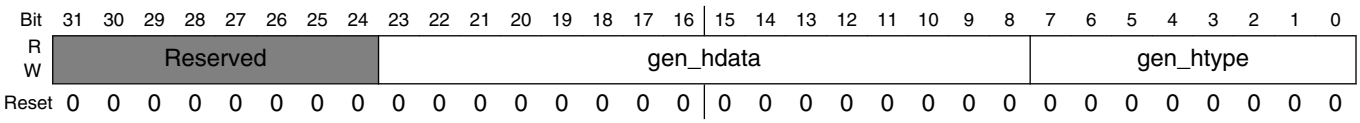
41.6.14 Generic packet Header configuration (MIPI_DSI_GEN_HDR)

Size: 32 bits

Offset: 0x34

Memory Access: R/W

Address: 21E_0000h base + 34h offset = 21E_0034h



MIPI_DSI_GEN_HDR field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–8 gen_hdata	Configures the packet data to be transmitted through the generic interface
gen_htype	Configures the packet type to be transmitted through the generic interface. Writing to this register triggers packet transmission (Payload must be written in advance)

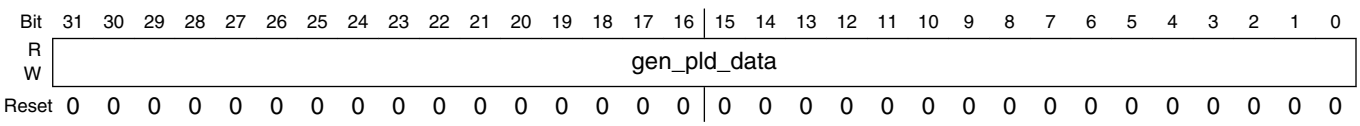
41.6.15 Generic payload data in/out (MIPI_DSI_GEN_PLD_DATA)

Size: 32 bits

Offset: 0x38

Memory Access: R/W

Address: 21E_0000h base + 38h offset = 21E_0038h



MIPI_DSI_GEN_PLD_DATA field descriptions

Field	Description
gen_pld_data	This register contains the input/output generic packet data. Write access to it writes the content of the packet payload. Read access reads the incoming generic read data

41.6.16 Command packet status (MIPI_DSI_CMD_PKT_STATUS)

Size: 32 bits

Offset: 0x3c

Memory Access: R/W

Address: 21E_0000h base + 3Ch offset = 21E_003Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MIPI_DSI_ERROR_ST1 field descriptions

Field	Description
31–18 -	This field is reserved. Reserved
17 dbi_illegal_comm_err	Attempt to write an illegal command on the DPI interface and core blocked by transmission
16 dbi_pld_recv_err	During a DBI read back packet, the payload FIFO went full and received data was corrupted
15 dbi_pld_rd_err	During a DCS read data, the payload FIFO went empty and data was send to the interface corrupted
14 dbi_pld_wr_err	System tried to write payload data through the DBI interface and the FIFO was full, therefore the Command was not written
13 dbi_cmd_wr_err	System tried to write a command through the DBI but the command FIFO was full, therefore the command was not written
12 gen_pld_recv_err	During a generic interface packet read back, the payload FIFO went full and received data was corrupted
11 gen_pld_rd_err	During a DCS read data, the payload FIFO went empty and data was send to the interface corrupted
10 gen_pld_send_err	During a generic interface packet build, the payload FIFO went empty and data was sent corrupted
9 gen_pld_wr_err	System tried to write a payload data through the generic interface and FIFO was full, therefore the payload was not written
8 gen_cmd_wr_err	System tried to write a command through the generic interface and FIFO was full, therefore the command was not written
7 dpi_pld_wr_err	During a DPI pixel line storage the payload FIFO went full and data stored is corrupted
6 eopt_err	EOTp Packet not received at the end of the incoming peripheral transmission
5 pkt_size_err	Packet size error was detected during packet reception
4 crc_err	CRC error was detected in the received packet payload
3 ecc_multi_err	ECC multiple error was detected in a received packet
2 ecc_sinlge_err	ECC single error was detected and corrected in a received packet
1 to_lp_rx	Low Power Reception Time Out Counter reached the end and Contention Detection as been detected
0 to_hs_tx	High Speed Transmission Time Out Counter reached the end and Contention Detection as been detected

phy_testdin	PHY test interface input 8-bit data bus for internal register programming and test functionalities access

Chapter 42
MIPI HSI Host Controller (MIPI_HSI)

42.1 Overview

MIPI_HSI is an interface intended to connect an application processor to a cellular modem controller in cellular handsets, but it can be used in other applications.

This document describes the micro-architecture for the MIPI_HSI host controller and the block level functionality and implementation in detail.

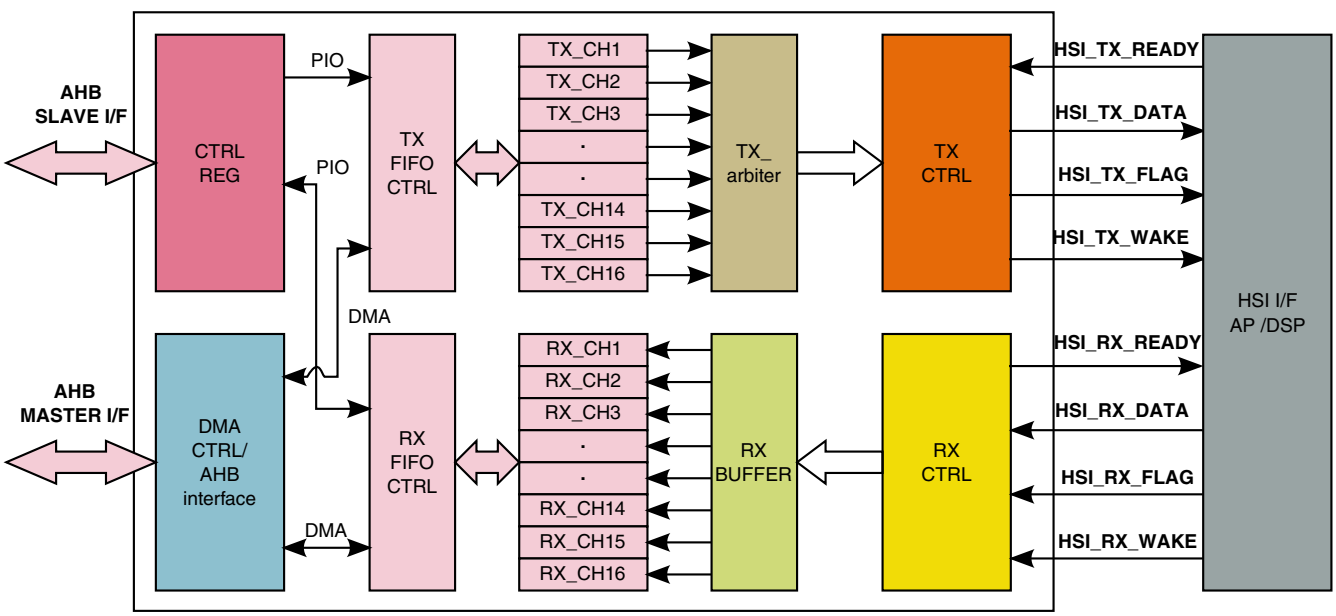

Figure 42-1. Top-Level Architecture

42.1.1 Features

The features of MIPI_HSI include the following:

- AHB slave interface support for PIO and configure.
- Supports PIO and DMA access mode
- Supports AHB Master interface to SOC interconnect
- Compatible with the MIPI_HSI specification version1.0 & MIPI_HSI Physical Layer v1.01.00 specification
- Full-Duplex High Speed Serial interface
- Supports 16 logical channels for both transmit and receive operations
- Each channel is configurable and can be enabled and disabled
- Bandwidth for each channel is programmable
- Supports both stream mode and frame mode for data transmission and reception
- Maximum bandwidth up to 100Mbs in both transmit and receive directions
- Configurable transmit and receive FIFO
- Programmable transmission bit rate
- Support round-robin arbitration for transmission mode
- Run-time configurability of channel ID bits
- Data time out feature supported for receive operation

42.2 External Signals

42.2.1 External Signals Overview

MIPI_HSI has 8 associate I/O signals.

- HSI_RX_DATA: Serial data bus
- HSI_RX_FLAG: Flag signal. If data on HSI_RX_DATA is toggling then flag stays constant and if data is constant then flag should toggle. It can be used with HSI_RX_DATA.
- HSI_RX_READY: Link data flow control signal. It indicates HSI RX is ready to receive.
- HSI_RX_WAKE: Link Control signal used to wake up the receiver.
- HSI_TX_DATA: Serial data out
- HSI_TX_FLAG: Flag signal. If data on HSI_TX_DATA is toggling, then flag stays constant and if data is constant, then flag should toggle.
- HSI_TX_READY: Link data flow control signal. It indicates HSI RX of other die is ready.
- HSI_TX_WAKE: Assertion of this signal shows that HSI TX wants to transfer some data. This signal is used to wake up HSI RX of other die.

42.2.2 Ports Table

See the following table for the signal properties of the I/Os.

Table 42-1. Properties of I/O Signals

Name	Port	Function	Reset State	Pull up
HSI_RX_DATA	I	Serial data bus	N/A	N/A
HSI_RX_FLAG	I	Flag signal. If data on HSI_RX_DATA is toggling then flag stays constant and if data is constant then flag should toggle. It can be used with HSI_RX_DATA.	N/A	N/A
HSI_RX_READY	O	Link data flow control signal. It indicates HSI RX is ready to receive	N/A	N/A
HSI_RX_WAKE	I	Link Control signal used to wake up the receiver so that transmitter starts a transmission	N/A	N/A
HSI_TX_DATA	O	Serial data out	0	N/A
HSI_TX_FLAG	O	Flag signal. If data on tx_data is toggling, then flag stays constant and if data is constant, then flag should toggle.	0	N/A
HSI_TX_READY	I	Link data flow control signal. It indicates HSI RX of other die is ready	N/A	N/A
HSI_TX_WAKE	O	Assertion of this signal shows that HSI TX wants to transfer some data. This signal is used to wake up HSI RX of other die	0	N/A

42.3 Clocks

The table found here describes the clock sources for MIPI HSI.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 42-2. MIPI HSI Clocks

Clock name	Clock Root	Description
h_clk	ahb_clk_root	AHB clock
tx_ref_clk	hsi_tx_clk_root	Tx reference clock

42.4 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Channel Buffer, DMA AHB interface, register bank as well as AHB slave Bus interface, dual-port memory wrapper, clock & reset manager and clock generator.

42.4.1 DMA AHB /PIO AHB slave and Data Channel Buffer

The HSI uses one configurable data buffer so data can be transferred between the system bus (AHB slave Bus or AHB Master Bus) and the HSI controller.

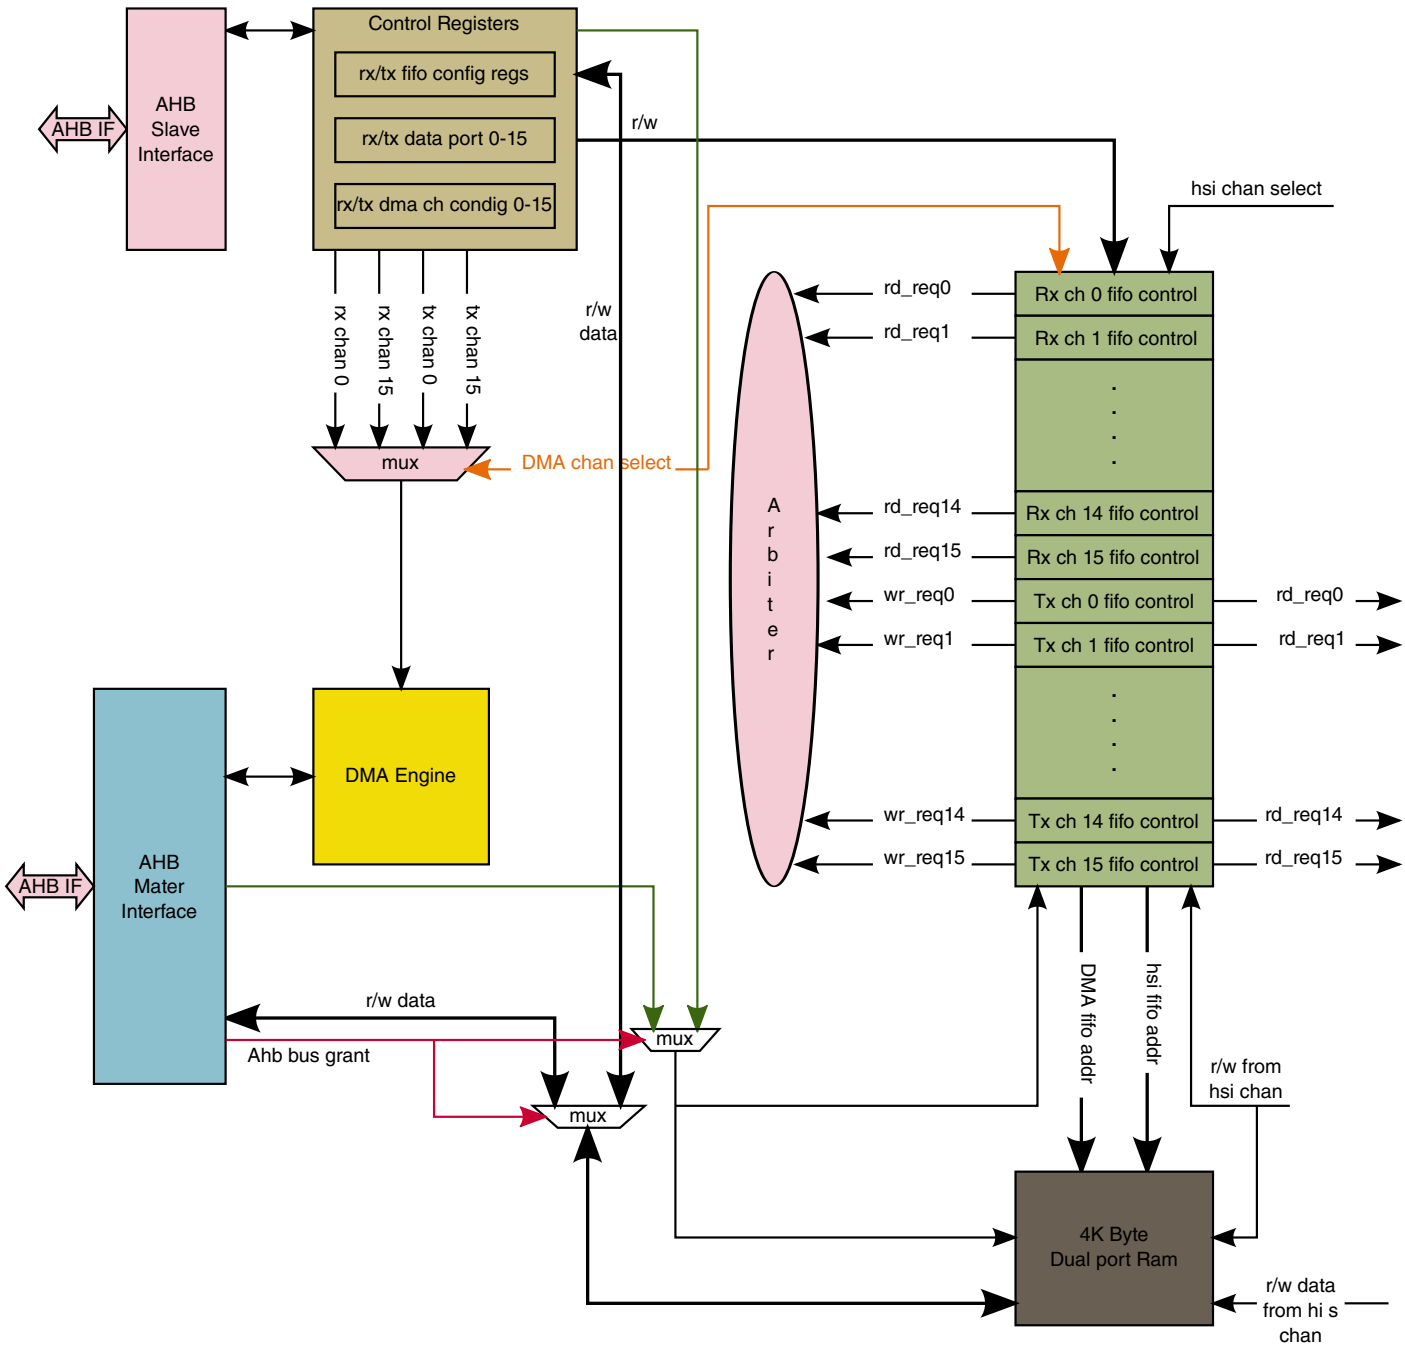

Figure 42-2. HSI DMA AHB/PIO AHB slave and data channel Buffer Scheme

42.4.1.1 AHB Slave Interface

This interface is compatible with AMBA AHB2.0 interface.

42.4.1.2 AHB Master Interface

This block access bus data by burst 8, burst 4 or single. AHB bus error is support.

42.4.1.3 Control Registers

This block has all the control registers of HSI Controller.

42.4.1.4 DMA Engine

This block generate DMA commands and send it to AHB master interface. These DMA commands are generated according current DMA channel configuration registers. AHB Master Interface should access AHB bus according the commands.

42.4.1.5 Rx/Tx FIFO controller

There are 32 sets of Rx/Tx FIFO Controller. Each FIFO Controller is corresponding to a Rx/Tx channel and a DMA channel. The depth for Each FIFO Controller is configurable. Once the number of data in the FIFO is less (for Tx) or more (for Rx) than the burst length of the corresponding DMA channel, it will send wr_req/rd_req signal to the Arbiter.

42.4.1.6 Arbiter

The arbiter arbitrates the requests from all 32 FIFO controllers according round robin priority.

42.4.1.7 4K Bytes Dual Port RAM

This block is used to save all FIFO data.

42.4.1.8 Typical Software Operation Flow for DMA

1. Configure Tx/Rx FIFO Size Configuration Registers. The total size of the FIFOs should not more than 1K DWords.

2. Enable RDMA/TDMA channel Complete Irq and Error Irq.

3. Configure RDMA/TDMA Start Address, Burst Size and Trans_length for each DMA channel. After that, set the RDMA/TDMA Enable bit. Once the Enable bit is set, the DMA channel will start to work right away.

4. Wait HSI Controller Irq and check RDMA/TDMA Complete Irq Stat bit.

42.4.1.9 Typical Software Operation Flow 1 for Data Port

1. Read corresponding Tx/Rx FIFO Status Register to make sure FIFO isn't empty/full.

2. Read/write Tx/Rx channel Data Port registers to access channel FIFO data.

42.4.1.10 Typical Software Operation Flow 2 for Data Port

1. Configure corresponding Tx/Rx FIFO Threshold Register.

2. Enable Tx/Rx FIFO Threshold interrupt.

3. Wait Tx/Rx FIFO Threshold interrupt.

4. Read/write Tx/Rx channel Data Port registers to access channel FIFO data.

42.4.2 HSI Reset

There are two kinds of reset signals within HSI:

1. Hardware reset
2. Software reset for all

These signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

This module controls all the reset signals within the HSI.

42.5 HSI Memory Map/Register Definition

This section includes the module memory map and detailed descriptions of all registers.

NOTE

The HSI registers are 32 bits wide and only support 32-bit access.

NOTE

The term reset refers to power-on-reset. It will be specified whenever the software reset value differs from the power-on-reset.

MIPI_HSI memory map

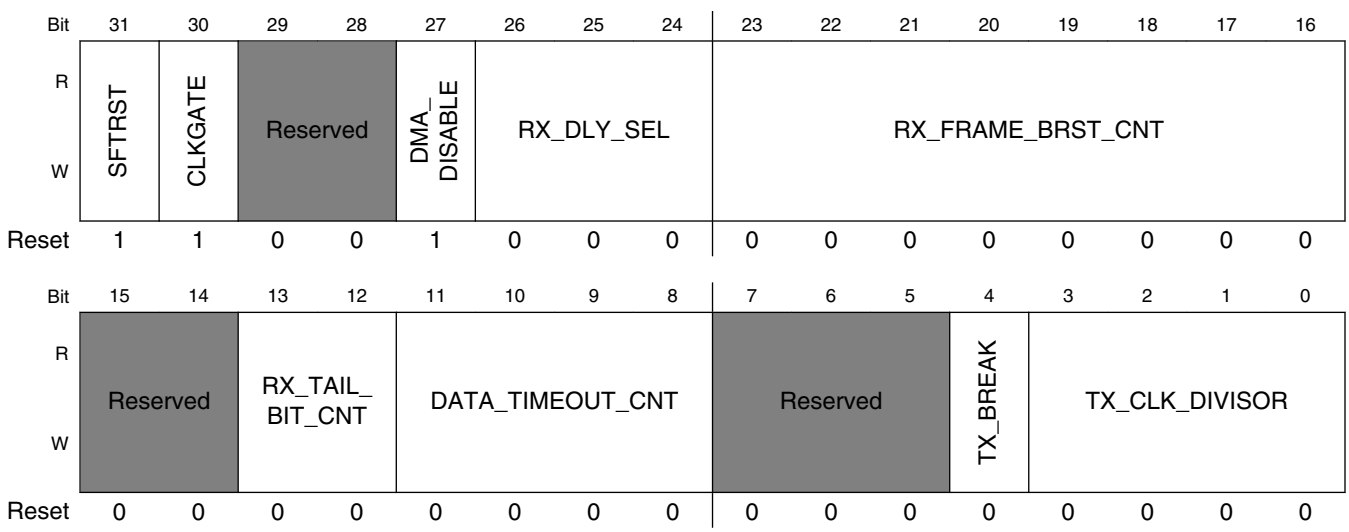
42.5.1 HSI Control Register (MIPI_HSI_CTRL)

This register contains module soft reset, clock gating, clock divisor and so on.

Address: 220_8000h base + 0h offset = 220_8000h



MIPI_HSI_CTRL field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal HSI operation. Set this bit to one (default) to disable clocking with the HSI and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the HSI block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.

Table continues on the next page...

MIPI_HSI_CTRL field descriptions (continued)

Field	Description
29–28 Reserved	This field is reserved. Reserved, always set to zero.
27 DMA_DISABLE	This bit must be set to zero for any DMA operation. When set to one it disabel all the DMA channels.
26–24 RX_DLY_SEL	These values denote the tap delay values for reception of data and flag. 000 0ns ; 001 1ns ; 010 2ns ; 011 3ns ; 100 4ns ; 101 5ns ; 110 6ns ; 111 7ns ;
23–16 RX_FRAME_ BRST_CNT	This value is to limit the continous Frame transmission count in Pipelined Data flow. The Receiver Frame Burst counter shall be able to support upto 256 frames of continous transfer. 7'h00 256 frames transmission count is set. 7'h01 1 frames transmission count is set. 7'h02 2 frames transmission count is set. 7'hff 255 frames transmission count is set.
15–14 Reserved	This field is reserved. Reserved.
13–12 RX_TAIL_BIT_ CNT	The value determines the length of the Tailing bit counter. The receiver shall start Receiver Tailing bit counter after the nth frame programmed in Rx Frame Burst counter is received. The receiver shall then drive ready to logic one if the receiver Tailing-bit counter has completed with no errors detected, and the receiver has enough room for at least one new frame. 00 800-> tx_refclk 01 400-> tx_refclk 10 200-> tx_refclk 11 100-> tx_refclk
11–8 DATA_ TIMEOUT_CNT	This value determines the interval by which DATA timeouts are detected. This data timeout counter logic is used only for Receive operations. The counter should start counting when data in any of the RX channel fifo is less than the threshold value and resets to zero when there is a threshold reached interrupt from any of the RX buffers. The counter value should be zero, when RX fifo is empty. An interrupt will be asserted to the host driver, when the counter value reaches the data timeout counter value. 1110 HSI Tx Clock x 2 ^ 27 0001 HSI Tx Clock x 2 ^ 14 0000 HSI Tx Clock x 2 ^ 13

Table continues on the next page...

MIPI_HSI_CTRL field descriptions (continued)

Field	Description
7–5 Reserved	This field is reserved. Reserved.
4 TX_BREAK	Seeting this bit to one trigger a transmission break at HSI Tx. Once this bit is set to one, the HSI controller will send a serise zeros on HSI_TX_DATA port according to the tx break co unt. It will be automatically cleared, when the send is finished.
TX_CLK_ DIVISOR	This register holds the divisor of the base clock (tx_refclk) frequency for HSI Tx clock (internal clock used to drive Transmitter interface). 1000 tx_refclk divided by 256 0111 tx_refclk divided by 128 0110 tx_refclk divided by 64 0101 tx_refclkdivided by 32 0100 tx_refclk divided by 16 0011 tx_refclk divided by 8 0010 tx_refclk divided by 4 0001 tx_refclk divided by 2 0000 tx_refclk divided by 1

42.5.2 HSI Tx Config Register (MIPI_HSI_TX_CONF)

This register contains the configurations of tx channel enable/disable, tx wakup and tx trans mode.

Address: 220_8000h base + 4h offset = 220_8004h

MIPI_HSI_CH_SFTRST field descriptions

Field	Description
31 TX_CH15	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 15 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
30 TX_CH14	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 14 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
29 TX_CH13	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 13 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
28 TX_CH12	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 12 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
27 TX_CH11	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 11 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
26 TX_CH10	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 10 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
25 TX_CH9	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 9 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.

Table continues on the next page...

MIPI_HSI_CH_SFTRST field descriptions (continued)

Field	Description
24 TX_CH8	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 8 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
23 TX_CH7	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 7 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
22 TX_CH6	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 6 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
21 TX_CH5	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 5 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
20 TX_CH4	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 4 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
19 TX_CH3	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 3 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
18 TX_CH2	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 2 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
17 TX_CH1	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 1 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
16 TX_CH0	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Tx Channel 0 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
15 RX_CH15	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 15 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
14 RX_CH14	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 14 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
13 RX_CH13	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 13 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
12 RX_CH12	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 12 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
11 RX_CH11	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 11 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
10 RX_CH10	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 10 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
9 RX_CH9	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 9 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
8 RX_CH8	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 8 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
7 RX_CH7	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 7 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
6 RX_CH6	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 6 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
5 RX_CH5	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 5 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
4 RX_CH4	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 4 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
3 RX_CH3	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 3 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
2 RX_CH2	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 2 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.

Table continues on the next page...

MIPI_HSI_CH_SFTRST field descriptions (continued)

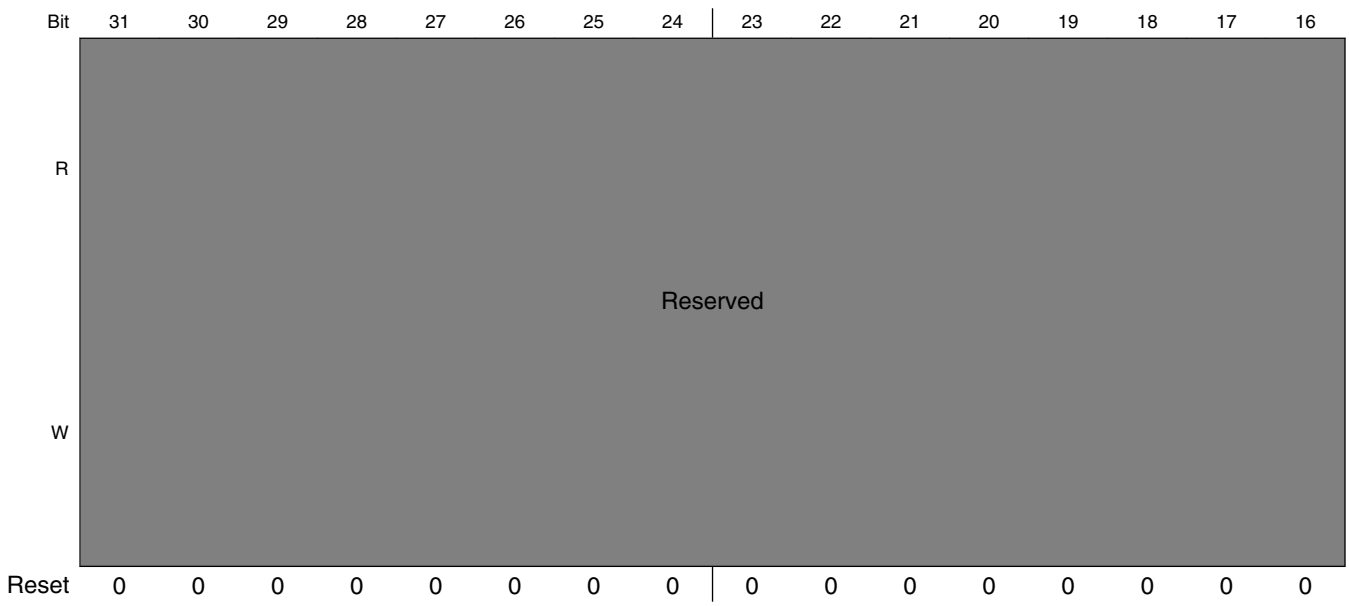
Field	Description
1 RX_CH1	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 1 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.
0 RX_CH0	Set this bit to zero to enable normal HSI operation. Set this bit to one to reset Rx Channel 0 (DMA and Fifo). When the reset operation complete, this bit will turn to zero automatically.

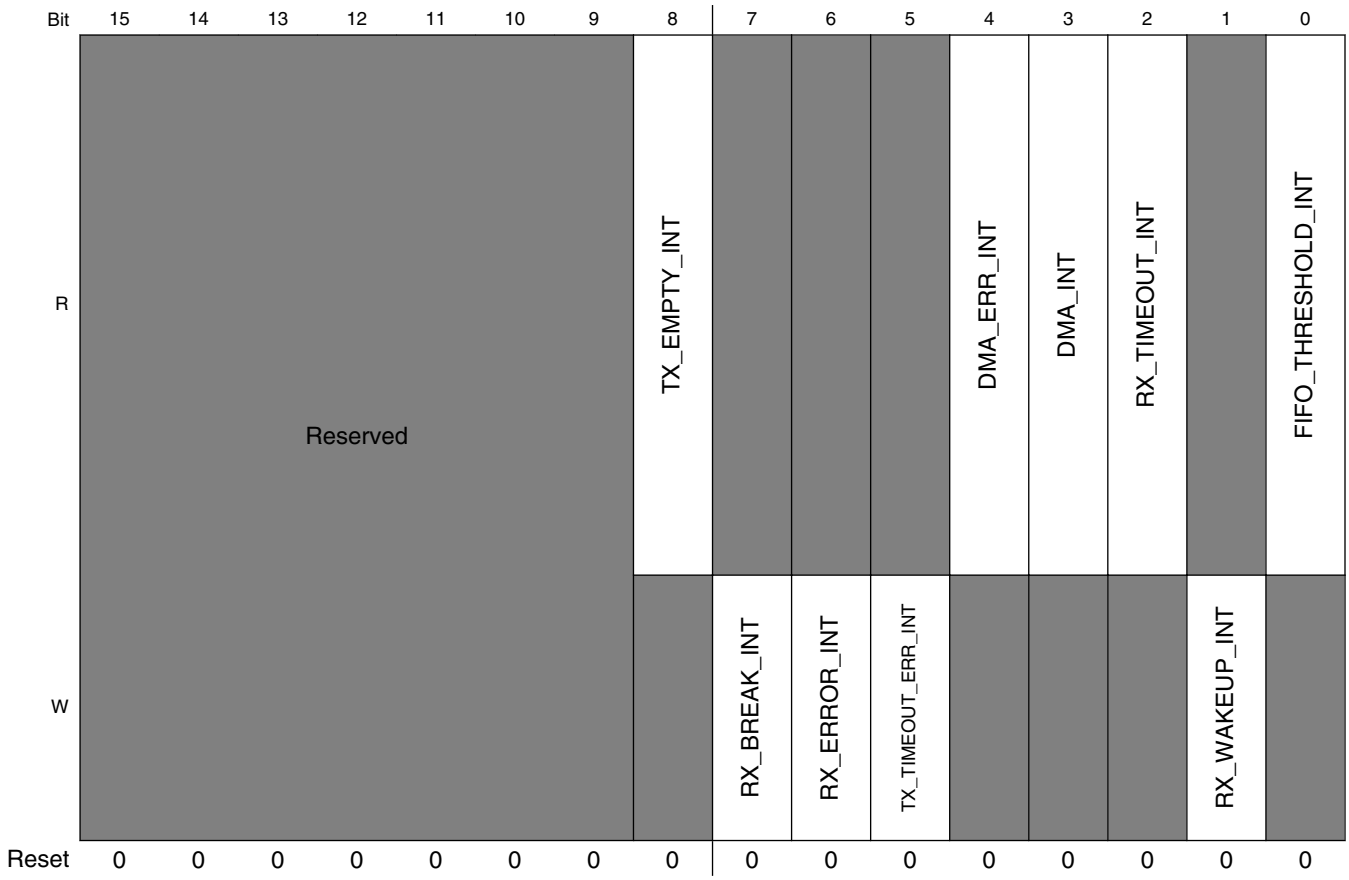
42.5.13 HSI Interrupt Status Register (MIPI_HSI_IRQSTAT)

This is HSI controller Interrupt Status Register.

This register contains the HSI controller Interrupt Status.

Address: 220_8000h base + 30h offset = 220_8030h





MIPI_HSI_IRQSTAT field descriptions

Field	Description
31–9 Reserved	This field is reserved. Reserved, always set to zero.
8 TX_EMPTY_INT	1 All tx channel empty and tx state IDLE Interrupt Status 0 not All tx channel empty and tx state IDLE Interrupt Status
7 RX_BREAK_INT	0 No Error. 1 Error.
6 RX_ERROR_INT	0 No Error. 1 Error.
5 TX_TIMEOUT_ERR_INT	0 No Error. 1 Error.
4 DMA_ERR_INT	If any bit in the DMA Error Interrupt Status Register is set, then this bit is set. on seeing this bit set, the ocp driver will read the Error Interrupt Staus Register. 0 No Error. 1 Error.
3 DMA_INT	This bit is set when a Transmit or Receive Operation is completed for DMA.

Table continues on the next page...

MIPI_HSI_IRQSTAT field descriptions (continued)

Field	Description
2 RX_TIMEOUT_INT	If any bit in the HSI Error Interrupt Status Register is set, then this bit is set. on seeing this bit set, the ocp driver will read the Error Interrupt Staus Register. 0 No Error. 1 Error.
1 RX_WAKEUP_INT	1 Receiver Wakeup event is occurred 0 Receiver Wakeup event is not occurred
0 FIFO_THRESHOLD_INT	1 Threshold amount of data reached in TX/Rx FIFO Interrupt Status 0 Threshold amount of data not reached in TX/Rx FIFO Interrupt Status

42.5.14 HSI Interrupt Status Enable Register (MIPI_HSI_IRQSTAT_EN)

This register contains the HSI controller Interrupt Status Enable.

Address: 220_8000h base + 34h offset = 220_8034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31–9 Reserved	This field is reserved. Reserved, always set to zero.

Table continues on the next page...

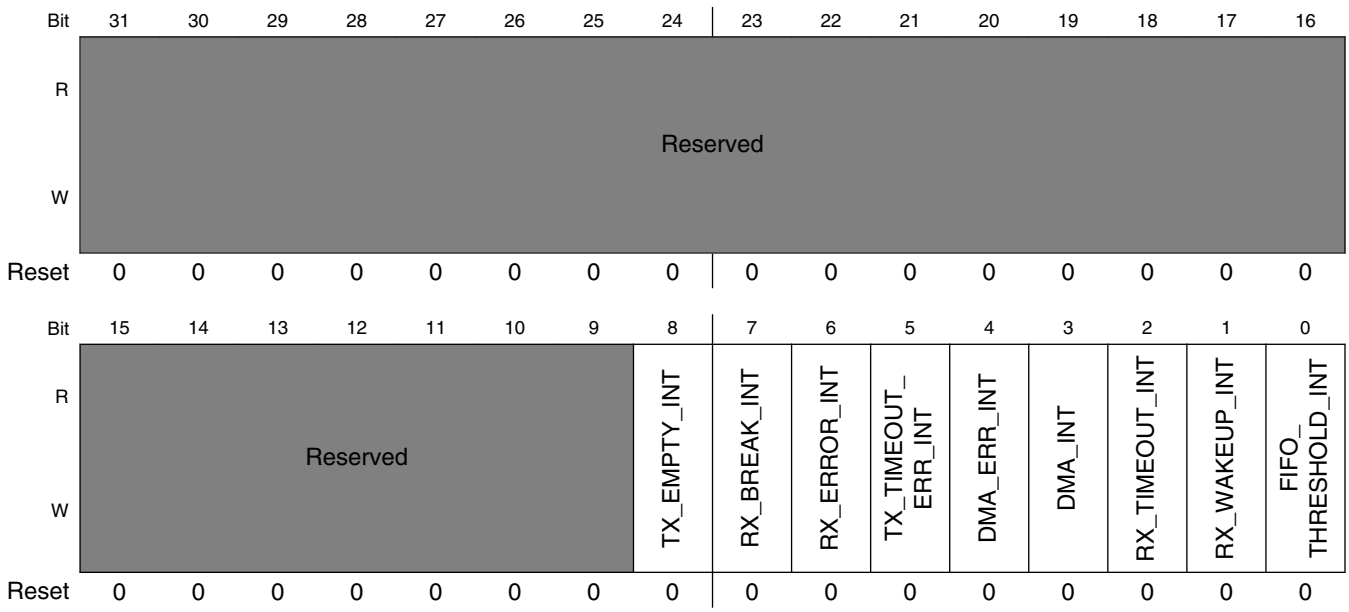
MIPI_HSI_IRQSTAT_EN field descriptions (continued)

Field	Description
8 TX_EMPTY_INT	1 Interrupt status enabled for TX_EMPTY_INT_STATUS interrupt. 0 Interrupt status masked TX_EMPTY_INT_STATUS interrupt.
7 RX_BREAK_INT	1 Interrupt status enabled for RX_BREAK status interrupt. 0 Interrupt status masked RX_BREAK status interrupt.
6 RX_ERROR_INT	1 Interrupt status enabled for RX_ERROR status interrupt. 0 Interrupt status masked RX_ERROR status interrupt.
5 TX_TIMEOUT_ERR_INT	1 Interrupt status enabled for TX_TIMEOUT_ERR status interrupt. 0 Interrupt status masked TX_TIMEOUT_ERR status interrupt.
4 DMA_ERR_INT	1 Interrupt status enabled for DMA_ERROR_INT_STATUS interrupt. 0 Interrupt status masked DMA_ERROR_INT_STATUS interrupt.
3 DMA_INT	1 Interrupt status enabled for DMA_INT_STATUS interrupt. 0 Interrupt status masked DMA_INT_STATUS interrupt.
2 RX_TIMEOUT_INT	1 Interrupt status enabled for RX_TIMEOUT_INT_STATUS interrupt. 0 Interrupt status masked RX_TIMEOUT_INT_STATUS interrupt.
1 RX_WAKEUP_INT	1 Interrupt status enabled for RX_WAKEUP_INT_STATUS interrupt. 0 Interrupt status masked RX_WAKEUP_INT_STATUS interrupt.
0 FIFO_THRESHOLD_INT	1 Interrupt status enabled for FIFO_THRESHOLD_INT_STATUS interrupt. 0 Interrupt status masked FIFO_THRESHOLD_INT_STATUS interrupt.

42.5.15 HSI Interrupt Signal Enable Register (MIPI_HSI_IRQSIG_EN)

This register contains the HSI controller Interrupt Signal Enable.

Address: 220_8000h base + 38h offset = 220_8038h



MIPI_HSI_IRQSIG_EN field descriptions

Field	Description
31–9 Reserved	This field is reserved. Reserved, always set to zero.
8 TX_EMPTY_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for HSI TX_EMPTY interrupt. 0 Interrupt signal masked for HSI TX_EMPTY interrupt.
7 RX_BREAK_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for RX_BREAK interrupt. 0 Interrupt signal masked for RX_BREAK interrupt.
6 RX_ERROR_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for RX Error interrupt. 0 Interrupt signal masked for RX Error interrupt.
5 TX_TIMEOUT_ERR_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for TX Timeout Error interrupt. 0 Interrupt signal masked for TX Timeout Error interrupt.

Table continues on the next page...

MIPI_HSI_IRQSIG_EN field descriptions (continued)

Field	Description
4 DMA_ERR_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for DMA Error interrupt. 0 Interrupt signal masked for DMA Error interrupt.
3 DMA_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for DMA Completed interrupt. 0 Interrupt signal masked for DMA Completed interrupt.
2 RX_TIMEOUT_ INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for RX TIMEOUT interrupt. 0 Interrupt signal masked for RX TIMEOUT interrupt.
1 RX_WAKEUP_ INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for HSI RX Wakeup interrupt. 0 Interrupt signal masked for HSI RX Wakeup interrupt.
0 FIFO_ THRESHOLD_ INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for HSI FIFO_THRESHOLD interrupt. 0 Interrupt signal masked for HSI FIFO_THRESHOLD interrupt.

42.5.16 HSI FIFO Threshold Interrupt Status Register (MIPI_HSI_FIFO_THR_IRQSTAT)

This register contains the HSI controller FIFO Threshold Interrupt Status.

Field	Description
26 TX_CH10_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch10 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch10 threshold Reached interrupt.
25 TX_CH9_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch9 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch9 threshold Reached interrupt.
24 TX_CH8_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch8 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch8 threshold Reached interrupt.
23 TX_CH7_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch7 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch7 threshold Reached interrupt.
22 TX_CH6_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch6 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch6 threshold Reached interrupt.
21 TX_CH5_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch5 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch5 threshold Reached interrupt.
20 TX_CH4_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch4 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch4 threshold Reached interrupt.
19 TX_CH3_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch3 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch3 threshold Reached interrupt.
18 TX_CH2_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch2 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch2 threshold Reached interrupt.
17 TX_CH1_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch1 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch1 threshold Reached interrupt.
16 TX_CH0_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Tx Ch0 threshold Reached interrupt. 0 Interrupt signal masked for Tx Ch0 threshold Reached interrupt.
15 RX_CH15_INT	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for Rx Ch15 threshold Reached interrupt. 0 Interrupt signal masked for Rx Ch15 threshold Reached interrupt.

MIPI_HSI_ERR_IRQSTAT field descriptions

Field	Description
31 RX_CH15_ TIMEOUT_INT	This status bit is set when data timeout counter for ch15 reaches thedata timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch15 buffer and then read HSI Status register to find the further status of the Rx ch15 Buffer. The host driver has to read the Rx ch15 fifo on Dword basis, till the fifo is completely empty.

Table continues on the next page...

MIPI_HSI_ERR_IRQSTAT field descriptions (continued)

Field	Description
30 RX_CH14_ TIMEOUT_INT	This status bit is set when data timeout counter for ch14 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch14 buffer and then read HSI Status register to find the further status of the Rx ch14 Buffer. The host driver has to read the Rx ch14 fifo on Dword basis, till the fifo is completely empty.
29 RX_CH13_ TIMEOUT_INT	This status bit is set when data timeout counter for ch13 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch13 buffer and then read HSI Status register to find the further status of the Rx ch13 Buffer. The host driver has to read the Rx ch13 fifo on Dword basis, till thefifo is completely empty.
28 RX_CH12_ TIMEOUT_INT	This status bit is set when data timeout counter for ch12 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch12 buffer and then read HSI Status register to find the further status of the Rx ch12 Buffer. The host driver has to read the Rx ch12 fifo on Dword basis, till the fifo is completely empty.
27 RX_CH11_ TIMEOUT_INT	This status bit is set when data timeout counter for ch11 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch11 buffer and then read HSI Status register to find the further status of the Rx ch11 Buffer. The host driver has to read the Rx ch11 fifo on Dword basis, till the fifo is completely empty.
26 RX_CH10_ TIMEOUT_INT	This status bit is set when data timeout counter for ch10 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch10 buffer and then read HSI Status register to find the further status of the Rx ch10 Buffer. The host driver has to read the Rx ch10 fifo on Dword basis, till the fifo is completely empty.
25 RX_CH9_ TIMEOUT_INT	This status bit is set when data timeout counter for ch9 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch9 buffer and then read HSI Status register to find the further status of the Rx ch9 Buffer. The host driver has to read the Rx ch9 fifo on Dword basis, till the fifo is completely empty.
24 RX_CH8_ TIMEOUT_INT	This status bit is set when data timeout counter for ch8 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch8 buffer and then read HSI Status register to find the further status of the Rx ch8 Buffer. The host driver has to read the Rx ch8 fifo on Dword basis, till the fifo is completely empty.
23 RX_CH7_ TIMEOUT_INT	This status bit is set when data timeout counter for ch7 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch7 buffer and then read HSI Status register to find the further status of the Rx ch7 Buffer. The host driver has to read the Rx ch7 fifo on Dword basis, till the fifo is completely empty.
22 RX_CH6_ TIMEOUT_INT	This status bit is set when data timeout counter for ch6 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch6 buffer and then read HSI Status register to find the further status of the Rx ch6 Buffer. The host driver has to read the Rx ch6 fifo on Dword basis, till the fifo is completely empty.
21 RX_CH5_ TIMEOUT_INT	This status bit is set when data timeout counter for ch5 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch5 buffer and then read HSI Status register to find the further status of the Rx ch5 Buffer. The host driver has to read the Rx ch5 fifo on Dword basis, till the fifo is completely empty.
20 RX_CH4_ TIMEOUT_INT	This status bit is set when data timeout counter for ch4 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch4 buffer and then read HSI Status register to find the further status of the Rx ch4 Buffer. The host driver has to read the Rx ch4 fifo on Dword basis, till the fifo is completely empty.

Table continues on the next page...

MIPI_HSI_ERR_IRQSTAT field descriptions (continued)

Field	Description
19 RX_CH3_ TIMEOUT_INT	This status bit is set when data timeout counter for ch3 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch3 buffer and then read HSI Status register to find the further status of the Rx ch3 Buffer. The host driver has to read the Rx ch3 fifo on Dword basis, till the fifo is completely empty.
18 RX_CH2_ TIMEOUT_INT	This status bit is set when data timeout counter for ch2 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch2 buffer and then read HSI Status register to find the further status of the Rx ch2 Buffer. The host driver has to read the Rx ch2 fifo on Dword basis, till the fifo is completely empty.
17 RX_CH1_ TIMEOUT_INT	This status bit is set when data timeout counter for ch1 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch1 buffer and then read HSI Status register to find the further status of the Rx ch1 Buffer. The host driver has to read the Rx ch1 fifo on Dword basis, till the fifo is completely empty.
16 RX_CH0_ TIMEOUT_INT	This status bit is set when data timeout counter for ch0 reaches the data timeout counter value. On receiving the interrupt the host driver should read 1Dword of data from Rx ch0 buffer and then read HSI Status register to find the further status of the Rx ch0 Buffer. The host driver has to read the Rx ch0 fifo on Dword basis, till the fifo is completely empty.

31 RX_CH15_TIMEOUT_INT_EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch15 interrupt. 0 Interrupt signal masked for data timeout for ch15 interrupt.
30 RX_CH14_TIMEOUT_INT_EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch14 interrupt. 0 Interrupt signal masked for data timeout for ch14 interrupt.
29 RX_CH13_TIMEOUT_INT_EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch13 interrupt. 0 Interrupt signal masked for data timeout for ch13 interrupt.
28 RX_CH12_TIMEOUT_INT_EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch12 interrupt. 0 Interrupt signal masked for data timeout for ch12 interrupt.

Table continues on the next page...

MIPI_HSI_ERR_IRQSIG_EN field descriptions (continued)

Field	Description
27 RX_CH11_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch11 interrupt. 0 Interrupt signal masked for data timeout for ch11 interrupt.
26 RX_CH10_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch10 interrupt. 0 Interrupt signal masked for data timeout for ch10 interrupt.
25 RX_CH9_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch9 interrupt. 0 Interrupt signal masked for data timeout for ch9 interrupt.
24 RX_CH8_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch8 interrupt. 0 Interrupt signal masked for data timeout for ch8 interrupt.
23 RX_CH7_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch7 interrupt. 0 Interrupt signal masked for data timeout for ch7 interrupt.
22 RX_CH6_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch6 interrupt. 0 Interrupt signal masked for data timeout for ch6 interrupt.
21 RX_CH5_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch5 interrupt. 0 Interrupt signal masked for data timeout for ch5 interrupt.
20 RX_CH4_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch4 interrupt. 0 Interrupt signal masked for data timeout for ch4 interrupt.
19 RX_CH3_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch3 interrupt. 0 Interrupt signal masked for data timeout for ch3 interrupt.
18 RX_CH2_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch2 interrupt. 0 Interrupt signal masked for data timeout for ch2 interrupt.
17 RX_CH1_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch1 interrupt. 0 Interrupt signal masked for data timeout for ch1interrupt.
16 RX_CH0_ TIMEOUT_INT_ EN	Setting this bit will enable interrupt generation on interrupt line. 1 Interrupt signal enabled for data timeout for ch0 interrupt. 0 Interrupt signal masked for data timeout for ch0 interrupt.
Reserved	This field is reserved.

Table continues on the next page...

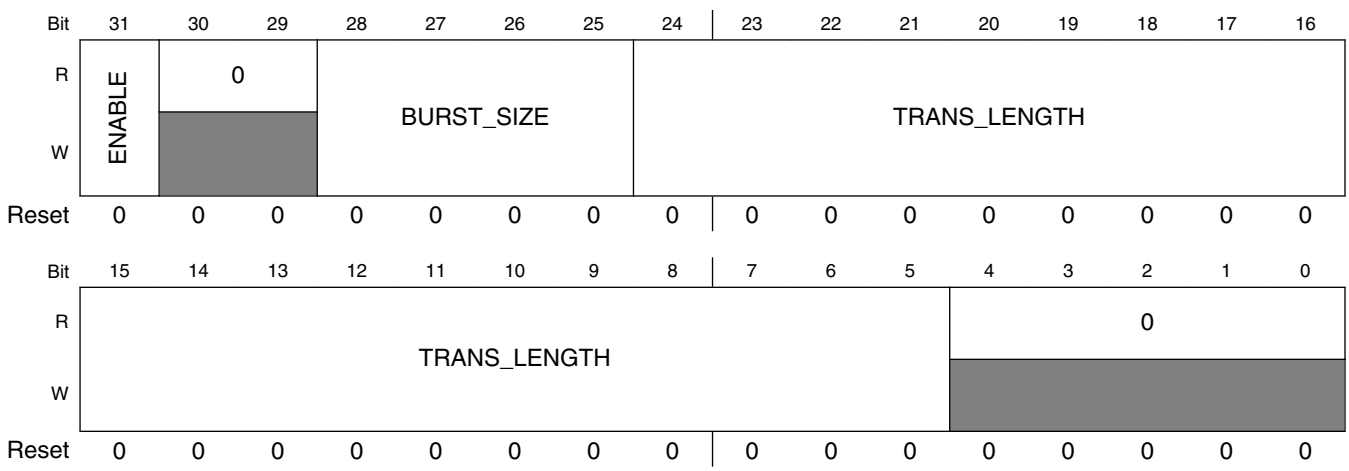
MIPI_HSI_ERR_IRQSIG_EN field descriptions (continued)

Field	Description
	Reserved, always set to zero.

42.5.24 Tx DMA Channel n Configuration Register (MIPI_HSI_TDMA*n*_CONF)

This register contains the configurations of enable/disable, burst size and transfer count for Tx DMA channel n.

Address: 220_8000h base + DCh offset + (4d × i), where i=0d to 15d



MIPI_HSI_TDMA*n*_CONF field descriptions

Field	Description
31 ENABLE	Setting this bit enables the inernal Tx DMA channel n.
30–29 Reserved	This read-only field is reserved and always has the value 0.
28–25 BURST_SIZE	Burst size for Tx DMA channel n. The unit is Dword. The burst size should not be larger than relevant TRANS_LENGTH and FIFO_SIZE. h0 1Dword to transfer for each burst h1 2Dword to transfer for each burst h2 4Dword to transfer for each burst h10 1024Dword to transfer for each burst
24–5 TRANS_ LENGTH	Transfer data length for Tx DMA channel n. The unit is Dword. h1 1Dword to transfer h2 2Dwords to transfer

Table continues on the next page...

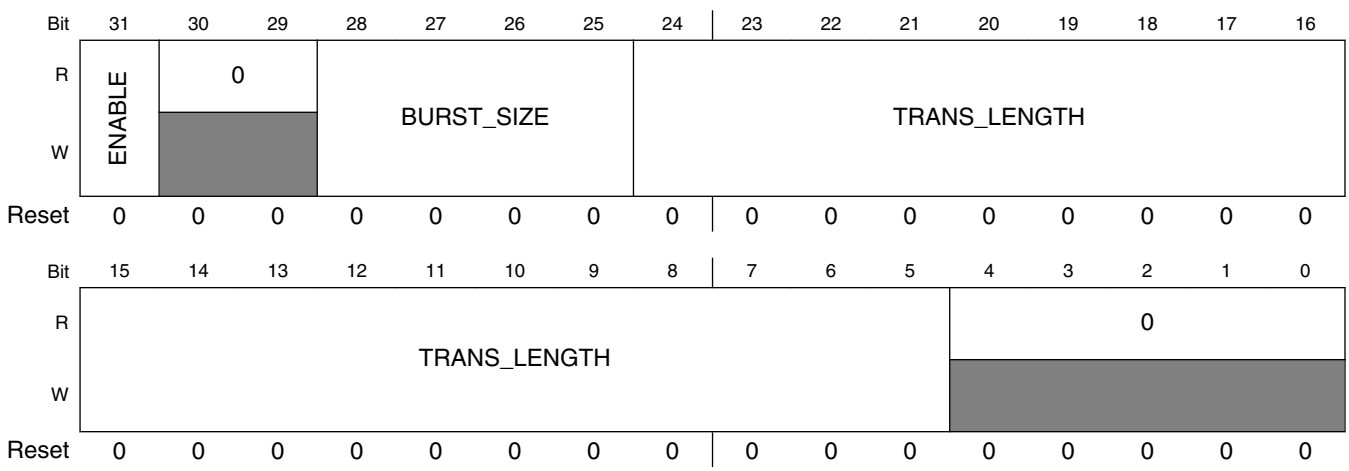
MIPI_HSI_TDMA*n*_CONF field descriptions (continued)

Field	Description
	hffffff 1048575Dwords to transfer
Reserved	This read-only field is reserved and always has the value 0.

42.5.25 Rx DMA Channel n Configuration Register (MIPI_HSI_RDMA*n*_CONF)

This register contains the configurations of enable/disable, burst size and transfer count for Rx DMA channel n.

Address: 220_8000h base + 11Ch offset + (4d × i), where i=0d to 15d



MIPI_HSI_RDMA*n*_CONF field descriptions

Field	Description
31 ENABLE	Setting this bit enables the inernal Rx DMA channel n.
30–29 Reserved	This read-only field is reserved and always has the value 0.
28–25 BURST_SIZE	Burst size for Rx DMA channel n. The unit is Dword. The burst size should not be larger than relevant TRANS_LENGTH and FIFO_SIZE. h0 1Dword to transfer for each burst h1 2Dword to transfer for each burst h2 4Dword to transfer for each burst h10 1024Dword to transfer for each burst
24–5 TRANS_ LENGTH	Transfer data length for Rx DMA channel 0. The unit is Dword. h1 1Dword to transfer

Table continues on the next page...

MIPI_HSI_RDMA*n*_CONF field descriptions (continued)

Field	Description
	h2 2Dwords to transfer hffffff 1048575Dwords to transfer
Reserved	This read-only field is reserved and always has the value 0.

42.5.26 Tx DMA Channel n Start Address Register (MIPI_HSI_TDMA*n*_STA_ADDR)

This Register containts the physical Start Address HSI for Tx DMA Channel n.

Address: 220_8000h base + 15Ch offset + (4d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MIPI_HSI_TX_BREAK_LEN field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved, always set to zero.
COUNT	The tx break length count. 6'h00 64 6'h01 1 6'h3f 63

Chapter 43
MediaLB (MLB)

43.1 Overview

The MLB150 implements the required functionality of a Media Local Bus (MediaLB) Device. Functionality includes:

- Transmission of commands and data when functioning as the transmitting device associated with a ChannelAddress
- Reception of data and transmission of RxStatus responses when functioning as the receiving device associated with a ChannelAddress
- MediaLB lock detection
- SystemChannel command handling

MediaLB Device functionality is implemented with an MediaLB 3-pin interface (single-ended) or MediaLB 6-pin interface (differential), however only one interface can be active at a time. The MediaLB interfaces are capable of exchanging data at speeds up to 1024xFs in 3-pin mode or 6144xFs in 6-pin mode.

A set of physical channels for exchanging data over the MediaLB bus is supported. These physical channels (4 bytes in length, or a quadlet) can be grouped into logical channels, where each logical channel is referenced using a ChannelAddress and represents a unidirectional data path between a specific MediaLB Device transmitting the data and the MediaLB Device(s) receiving the data. The MediaLB 6-pin interface provides support for up to 860 bytes of data per frame. The logical channels, configured by system software, can be any combination of channel types (synchronous, asynchronous, isochronous, or control) and direction (transmit or receive).

43.1.1 Block Diagram

The following figure is the top-level block diagram of the MLB150 behavioral models.

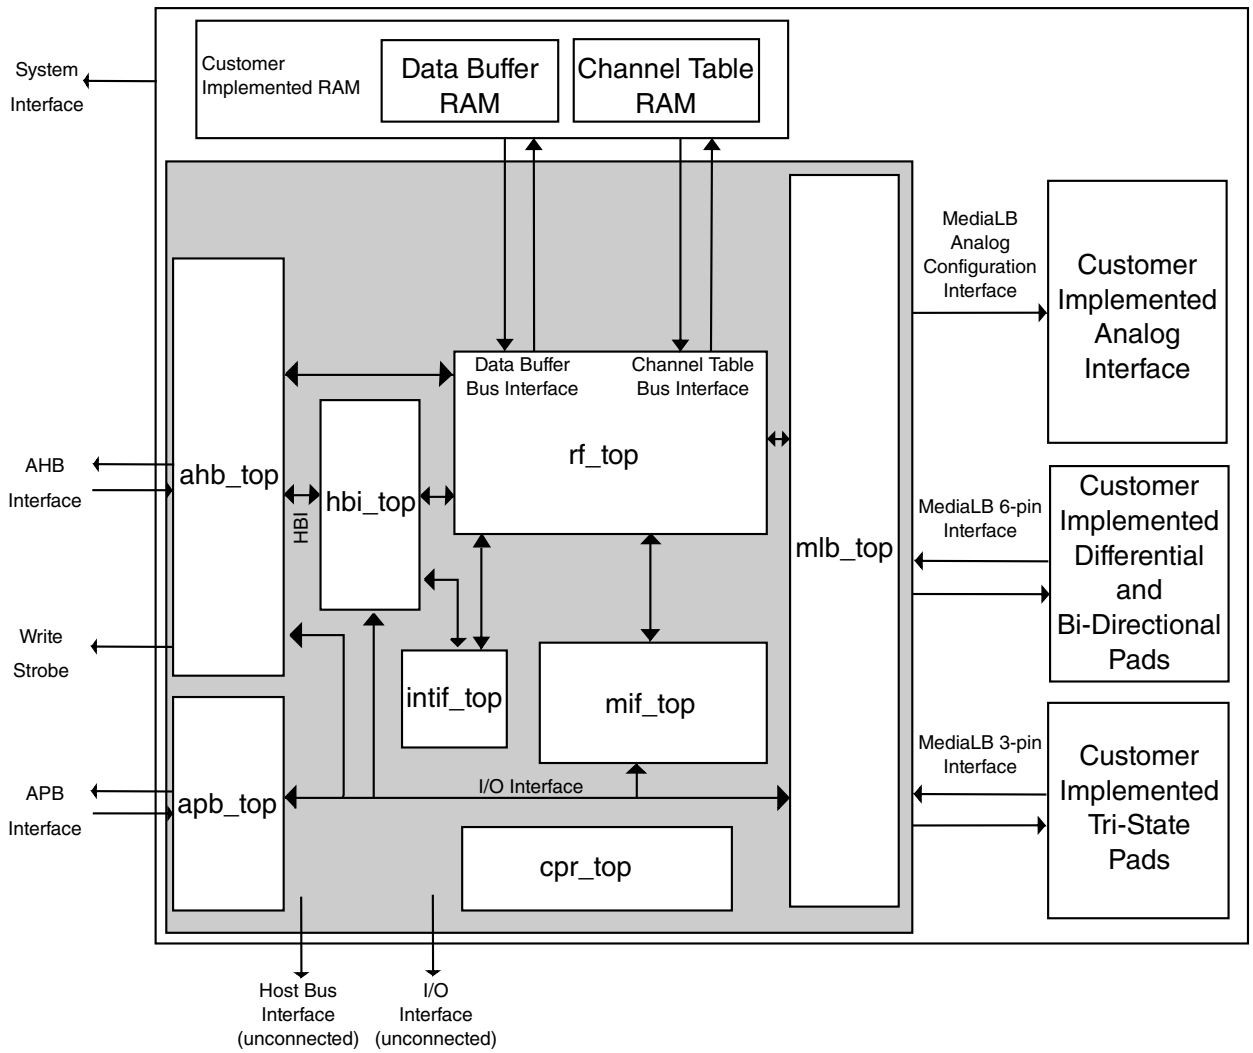

Figure 43-1. Block Diagram of MLB150

43.1.1.1 Bus Interfaces

The external bus interfaces include:

- MediaLB 3-pin Interface
- MediaLB 6-pin Interface
- MediaLB Analog Configuration Interface
- Channel Table Bus (CTB) Interface
- Data Buffer Bus (DBB) Interface
- System Interface

- AMBA Advanced High-performance Bus (AHB) Interface
- AMBA Advanced Peripheral Bus (APB) Interface

43.2 External Signals

The table found here describes the external signals of MLB150.

Table 43-1. MLB150 External Signals

Signal	Description	Pad	Mode	Direction
MLB_CLK	3-Wire clock signal	ENET_TXD1	ALT0	I
		GPIO_3	ALT7	
MLB_CLK_N	Negative clock signal	MLB_CN	No Muxing	I
MLB_CLK_P	Positive clock signal	MLB_CP	No Muxing	I
MLB_DATA	3-Wire data signal	ENET_MDC	ALT0	I/O
		GPIO_2	ALT7	
MLB_DATA_N	Negative data signal	MLB_DN	No Muxing	I/O
MLB_DATA_P	Positive data signal	MLB_DP	No Muxing	I/O
MLB_SIG	3-Wire signal	ENET_RXD1	ALT0	I/O
		GPIO_6	ALT7	
MLB_SIG_N	Negative signal	MLB_SIG_N	No Muxing	I/O
MLB_SIG_P	Positive signal	MLB_SIG_P	No Muxing	I/O

43.3 Clocks

The table found here describes the clock sources for MLB150.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 43-2. MLB150 Clocks

Clock name	Clock Root	Description
hclk	ahb_clk_root	AHB bus clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
sys_clk	axi_clk_root	Module clock
mem_ct_CLK	axi_clk_root	Channel table bus clock
mem_db_CLK	axi_clk_root	Data buffer bus clock

43.4 Functional Description

This section describes the functional architecture of the MLB150.

The internal functional blocks of the MLB150 include:

- MediaLB Block (mlb_top) - Implements the physical and link-layer requirements of either a MediaLB 3-pin or 6-pin interface. Serial-to-parallel and parallel-to-serial data transformations are implemented, as well as MediaLB frame synchronization
- Host Bus Interface Block (hbi_top) - Provides 16-bit parallel slave access to all MOST channels and data types for the external Host Controller (HC). The HBI supports up to 64 independent channels with a minimum access latency of 40 ns per word and a maximum bandwidth of 400 Mbps
- Routing Fabric Block (rf_top) - Manages the flow of data between the MediaLB block and the HBI block, implementing a bus arbiter and muxing logic to the Channel Table RAM (CTR) and the Data Buffer RAM (DBR)
- Memory Interface Block (mif_top) - Implements a bridge between the I/O bus and the customer-implemented RAMs (i.e. Channel Table and Data Buffer)
- Interrupt Interface Block (intif_top) - Sends notifications to HBI that there are changes to the channel descriptors
- Clocks, Power, and Reset Block (cpr_top) - Implements clock and reset muxing and synchronization
- AMBA AHB Block (ahb_top) - Implements a bus bridge between the AHB master and the HBI slave interfaces
- AMBA APB Block (apb_top) - Implements a bus bridge that translates the two cycle APB interface signals to the single-cycle I/O interface signals

43.4.1 MediaLB Block

The Media Local Bus (MediaLB) block supports both a MediaLB 3-pin interface and MediaLB 6-pin interface. However, only one MediaLB interface can be active at any given time. Both MediaLB interfaces provide real-time access to all network data types including streaming, packet, control, and isochronous data.

- MediaLB 3-pin Interface - Supports the MediaLB protocol for single-ended 3-pin mode, with a maximum data rate of 1024xFs (49.152 MHz at Fs=48 kHz).
- MediaLB 6-pin Interface - Supports the MediaLB protocol for high-speed differential 6-pin mode, with a maximum data rate of 6144xFs (294.912 MHz at Fs=48 kHz).

43.4.1.1 MediaLB Channel Address to Logical Channel Mapping

The MediaLB channel addresses are mapped to the logical channels as follows.

Table 43-3. MediaLB Channel Address to Logical Channel Mapping

Channel Address	Logical Channel
0x0002	1
0x0004	2
0x0006	3
....	....
0x007C	62
0x007E	63
0x01FE	0*
* Logical Channel 0 is the System Channel and is reserved.	

43.4.2 Host Bus Interface Block

The Host Bus Interface (HBI) block provides a 16-bit parallel slave port that provides an external Host Controller (HC) with access to all MOST channels and data types.

Up to 64 independent HBI channels are available to the HC, each configurable for either transmitting or receiving a particular application data type (synchronous, isochronous, asynchronous, or control). The HBI block provides source and sink access to the full network data bandwidth.

43.4.2.1 HBI Physical Addresses

To access a particular HBI DMA channel, hardware must first translate the HBI channel address to a channel allocation table (CAT) physical address. This physical address is then used to retrieve the channel label (CL), which in turn retrieves the channel descriptor.

See Table 43-4 for more information on the mapping between the HBI channel address and physical address.

Table 43-4. HBI Channel Address to Physical Address Mapping

HBI Channel	CAT Address	CAT Offset
0x0	0x88	000

Table continues on the next page...

Table 43-4. HBI Channel Address to Physical Address Mapping (continued)

HBI Channel	CAT Address	CAT Offset
0x1	0x88	001
0x2	0x88	010
0x3	0x88	011
0x4	0x88	100
0x5	0x88	101
0x6	0x88	110
0x7	0x88	111

43.4.3 Routing Fabric Block

The Routing Fabric (RF) block manages the flow of data between the MediaLB Port and the HBI Port. Bus multiplexers and a bus arbiter are implemented in the RF block for accessing the channel table RAM (CTR) and data buffer RAM (DBR).

Each DMA controller in the routing fabric uses Channel Descriptors (stored in the CTR) to manage access to dynamic buffers in the DBR.

43.4.3.1 Data Buffer RAM

The MLB150 has an external data buffer RAM (DBR) that is 8-bit x 16k entries deep. The DBR provides dynamic circular buffering between the transmit and receive devices.

The size and location of each data buffer is defined by software in the channel descriptor table (CDT), which is located in the CTR.

Receive devices retain the write address pointer to the associated circular data buffer in the DBR, while transmit devices retain the read address pointer. The DMA controllers in the routing fabric are responsible for ensuring that the circular buffers do not overflow or underflow. Each channel type (e.g. synchronous, isochronous, asynchronous and control) has Full and Empty detection.

43.4.3.1.1 Synchronous Channels

For synchronous channels, two mechanisms prevent overflow and underflow of the data buffer:

- Hardware aligns the read pointer (RPTR) to the write pointer (WPTR) to ensure an offset of two sub-buffers.
- RPTR and WPTR are periodically synchronized to the start of the next sub-buffer (e.g. following a FRAMESYNC).

43.4.3.1.2 Isochronous Channels

For isochronous channels, hardware does not read from an empty data buffer or write to a full data buffer. The conditions used by hardware for detection include:

Data buffer Empty condition: (RPTR = WPTR) AND (BF = 0), and

Data buffer Full condition: (WPTR = RPTR) AND (BF = 1).

43.4.3.1.3 Asynchronous and Control Channels

For asynchronous and control channels, hardware does not read from an empty data buffer or write to a full data buffer. Hardware evaluates the DMA pointers (RPTR, WPTR) and packet count (RPC, WPC) to detect the data buffer condition, where:

- Data buffer Empty condition: (RPTR = WPTR) AND (RPC = WPC), and
- Data buffer Full condition: ((WPTR = RPTR) AND (WPC != RPC)) OR (WPC = (RPC - 1)).

43.4.3.2 Channel Table RAM

The MLB150 has an external Channel Table RAM (CTR) that is 128-bit x 144-entry. The CTR allows system software to dynamically configure channel routing and allocate data buffers in the DBR.

The CTR is logically divided into three sub-tables:

- Channel Descriptor Table (CDT)
- AHB Descriptor Table (ADT)
- Channel Allocation Table (CAT)

43.4.3.2.1 Address Mapping

Table 43-5. CTR Address Mapping

Label	Address	Bits 127…96	Bits 95…64	Bits 63…32	Bits 31…0
Channel Descriptor Table (CDT):					
CDT	0x00	CDT0[127:0], CL = 0			
	0x01	CDT1[127:0], CL = 1			
	0x02	CDT2[127:0], CL = 2			
	...	...			
	0x3D	CDT61[127:0], CL = 61			
	0x3E	CDT62[127:0], CL = 62			
	0x3F	CDT63[127:0], CL = 63			
AHB Descriptor Table (ADT):					
ADT*	0x40	ADT0[127:0]			
	0x41	ADT1[127:0]			
	0x42	ADT2[127:0]			
	...	...			
	0x7D	ADT61[127:0]			
	0x7E	ADT62[127:0]			
	0x7F	ADT63[127:0]			
Channel Allocation Table (CAT):

CAT for HBI*	0x88	CAT71	CAT70	CAT69	CAT68	CAT67	CAT66	CAT65	CAT64
	...	...	...	...	...	...	...	...	...
	0x8F	CAT127	CAT126	CAT125	CAT124	CAT123	CAT122	CAT121	CAT120
* A fixed relationship exists between ADT entries and HBI CAT entries. When using HBI channel 0 (CAT64) on should program ADT0. When using HBI channel 1 (CAT65) on should program ADT1, and so on.									

43.4.3.2.2 Channel Allocation Table

The Channel Allocation Table (CAT) is comprised of 16 CTR entries (addresses 0x80 - 0x8F), as shown in Table 43-5. Each 16-bit CAT entry represents a logical connection to or from a transmit/receive device (e.g. MediaLB or HBI channel). All entries are indexed according to a fixed physical address assigned to every Rx/Tx channel (as shown in Table 43-6). The value stored in a CAT entry includes a 6-bit Connection Label, which provides a pointer to the CDT. To complete a logical channel and form a routing connection, system software must assign the same Connection Label to both the Rx and Tx channels.

Table 43-6. CAT Entry Map

Peripheral	Tx Channels	Rx Channels	CAT Start Index	CAT End Index	Entries
MediaLB	0 to 64	64 - Tx Channels	0	63	64
HBI	0 to 64	64 - Tx Channels	64	127	64

The format of a full CAT entry is shown in Table 43-7, with field descriptions described in Table 43-8. All reserved bits of a CAT entry field should be written as zero.

Table 43-7. CAT Entry Formats

Channel Type	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Isochronous	rsvd	FCE	rsvd	RNW	CE	CT[2:0] = 3			rsvd		CL[5:0]					
Asynchronous	rsvd		MT	RNW	CE	CT[2:0] = 2			rsvd		CL[5:0]					
Control	rsvd		MT	RNW	CE	CT[2:0] = 1			rsvd		CL[5:0]					
Synchronous	rsvd	MFE	MT	RNW	CE	CT[2:0] = 0			rsvd		CL[5:0]					

Table 43-8. CAT Field Definitions

Field	Description
CL[5:0]	Connection Label (offset into CDT)
CT[2:0]	Channel Type (Others): 111 = Reserved 110 = Reserved 101 = Reserved 100 = Reserved 011 = Isochronous 010 = Asynchronous 001 = Control 000 = Synchronous
CE	Channel Enable: 1 = Enabled 0 = Disabled
RNW	Read Not Write: 1 = Read 0 = Write
MT	Mute Enable: 1 1 = Enabled 0 = Disabled
FCE	Flow Control Enable: 2 1 = Enabled 0 = Disabled
MFE	Multi-Frame per Sub-buffer Enable: 3 1 = Enabled 0 = Disabled
rsvd	Reserved. Software writes a zero to all Reserved bits when the entry is initialized. The Reserved bits are Read-only after initialization.
1. When set for synchronous channels, the MT bit forces Rx channels to write zeros into the channel data buffer, and Tx channels to output zeros on the physical interface. When set for asynchronous and control channels, the MT bit causes DMA to halt at a packet boundary. Not valid for isochronous channels. 2. The FCE bit is used by MediaLB isochronous Rx channels only. 3. The MFE bit is used by MediaLB synchronous channels only.	

43.4.3.2.2.1 Channel Setup

Data direction in the MLB150 is in reference to the DBR. Therefore, the data direction of CAT entries corresponding to the same channel is reversed for the HBI CAT and the MediaLB CAT.

For a Tx channel (from the HC to the MediaLB interface):

- HBI CAT entry: RNW = 0 (write)
- MediaLB CAT entry: RNW = 1 (read)

Conversely, for a Rx channel (data from MediaLB to HC):

- HBI CAT entry: RNW = 1 (read)
- MediaLB CAT entry: RNW = 0 (write)

The figure below illustrates the directional relationship in the MLB150.

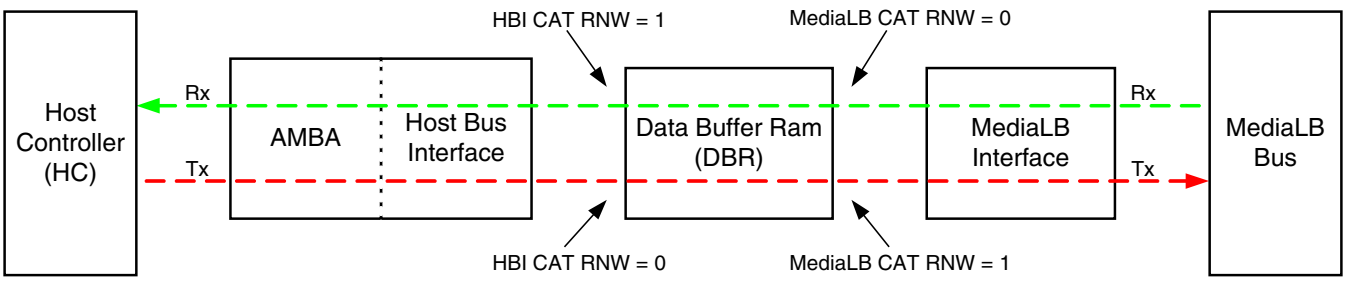

Figure 43-2. MLB DBR Directional Relationship

43.4.3.2.3 Channel Descriptor Table

The *Channel Descriptor Table* (CDT) is comprised of 64 CTR entries (addresses 0x00 - 0x3F), as shown in Table 43-5.

Each 128-bit CDT entry (also referred to as a *Channel Descriptor*) is referenced by a *Connection Label* and contains information about a data buffer in the DBR (e.g. buffer size, address pointers).

The format of each CDT entry (also referred to as a *Channel Descriptor*) is dependent on the channel type (e.g. synchronous, isochronous, asynchronous, or control).

NOTE

All reserved *Channel Descriptor* bits must be written to '0' by software when initialized.

43.4.3.2.3.1 Synchronous Channel Operation

A sample synchronous data buffer is shown in the figure found here.

A sample synchronous data buffer is shown in the figure below. Each data buffer contains four sub-buffers and each sub-buffer contains space for 1 to 64 frames of data, determined by MLBC0.FCNT[2:0].

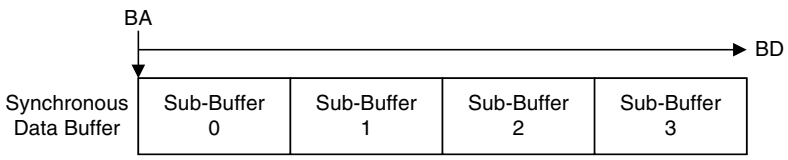

Figure 43-3. Synchronous Data Buffer Structure

43.4.3.2.3.2 Synchronous Channel Descriptors

The format and field definitions for a synchronous CDT entry are shown in the tables below respectively.

Table 43-9. Synchronous CDT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

96	Reserved				BD[11:0]											
112	Reserved		BA[13:0]													

Table 43-10. Synchronous CDT Entry Field Definitions

Field	Description	Details	Accessibility
BA	Buffer Base Address	- BA can start at any byte in the 16k DBR	r,w
BD	Buffer Depth	- BD = size of buffer in bytes - 1 - Buffer end address = BA + BD - BD = 4 x m x bpf - 1, where: m = frames per sub-buffer (for MFE = 0, m = 1) bpf = bytes per frame.	r,w
RPTR	Read Pointer	- Software initializes to zero, hardware updates - Counts the read address offset within a buffer - DMA read address = BA + RPTR	r,w,u
WPTR	Write Pointer	- Software initializes to zero, hardware updates - Counts the write address offset within a buffer - DMA write address = BA + WPTR	r,w,u

Table continues on the next page...

Table 43-10. Synchronous CDT Entry Field Definitions (continued)

Field	Description	Details	Accessibility
RSBC	Read Sub-buffer Counter	- Software initializes to zero, hardware updates - Counts the read sub-buffer offset - DMA uses for pointer management	r,w,u
WSBC	Write Sub-buffer Counter	- Software initializes to zero, hardware updates - Counts the write sub-buffer offset - DMA uses for pointer management	r,w,u
RSTS	Read Status	- Software initializes to zero, hardware updates - RSTS states:* xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle	r,w,u
WSTS	Write Status	- Software initializes to zero, hardware updates - WSTS states:* xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle 1xxx = command protocol error	r,w,u
Reserved	Reserved	- Software writes a zero to all *Reserved* bits when the entry is initialized. The *Reserved* bits are *Read-only* after initialization.	r,w,u
* Only valid for DMA pointers associated with the MediaLB block (Not valid for HBI block related pointers).			

43.4.3.2.3.3 Isochronous Channel Descriptors

The format and field definitions for an isochronous CDT entry are shown in the tables below respectively.

Table 43-11. Isochronous CDT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	Reserved															
16	Reserved															
32	Reserved							BS[8:0]								
48	Reserved															
64	WSTS[2:0]			WPTR[12:0]												
80	RSTS[2:0]			RPTR[12:0]												
96	Reserved			BD[12:0]												
112	BF	rsvd	BA[13:0]													

Table 43-12. Isochronous CDT Entry Field Definitions

Field	Description	Details	Accessibility
BA	Buffer Base Address	- BA can start at any byte in the 16k DBR	r,w
BD	Buffer Depth	- BD = size of buffer in bytes - 1 - Buffer end address = BA + BD - Isochronous buffers must be large enough to hold at least 3 blocks (packets) of data - Buffer depth must be a integer multiple of blocks	r,w
BF	Buffer Full	- Software initializes to zero, hardware updates - DMA write hardware sets BF when the buffer is full - DMA read hardware clears BF when the buffer is empty - BF is valid only when the buffer is full or empty, otherwise ignore	r,w,u
BS	Block Size	- BS defines when to begin the DMA to the data buffer - BS = buffer block size in bytes - 1 - For Rx channels, the DMA writes start when the number of empty bytes (SPACE) in the data buffer >= the block size - For Tx channels, the DMA reads start when the number of valid bytes (VALID) in the data buffer >= the block size	r,w,u
RPTR	Read Pointer	- Software initializes to zero, hardware updates - Counts the read address offset within a buffer - DMA read address = BA + RPTR	r,w,u
WPTR	Write Pointer	- Software initializes to zero, hardware updates - Counts the write address offset within a buffer - DMA write address = BA + WPTR	r,w,u
RSTS	Read Status	- Software initializes to zero, hardware updates - RSTS states:* xx1 = active xx0 = idle	r,w,u
WSTS	Write Status	- Software initializes to zero, hardware updates - WSTS states:* xx1 = active xx0 = idle x1x = command protocol error 1xx = buffer overflow (FCE = 0 only)	r,w,u
Reserved	Reserved	- Software writes a zero to all *Reserved* bits when the entry is initialized. The *Reserved* bits are *Read-only* after initialization.	r,w,u
* Only valid for DMA pointers associated with the MediaLB block (Not valid for HBI block related pointers).			

43.4.3.2.3.4 Asynchronous and Control Channel Descriptors

The format and field definitions for asynchronous and control CDT entries are shown in the tables below respectively.

Table 43-13. Asynchronous/Control CDT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	WPC[4:0]					Reserved

Field	Description	Details	Accessibility
		1xxxx = *ReceiverBreak* command received from Rx Device	
WSTS	Write Status	- Software initializes to zero, hardware updates - Status states:* x0x00 = idle xx1xx = command protocol error detected 1xxxx = *AsyncBreak*/*ControlBreak* command received from Tx Device	r,w,u
Reserved	Reserved	Software writes a zero to all *Reserved* bits when the entry is initialized. The *Reserved* bits are *Read-only* after initialization.	r,w,u
* Only valid for DMA pointers associated with the MediaLB block (Not valid for HBI block related pointers)			

43.4.4 Memory Interface Block

The Memory Interface (MIF) block implements a bridge between the I/O and the CTB or DBB interfaces.

The MIF block diagram is shown in the figure below. The targeted RAM (CTR or DBR) is determined by the target location bit in the memory address register (MADR.TB).

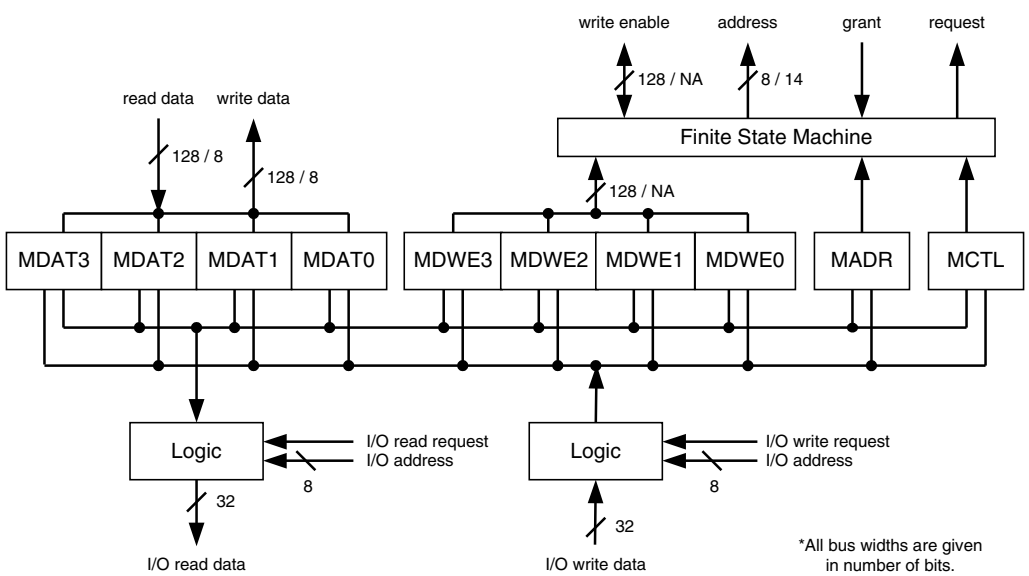

Figure 43-4. MIF Block Diagram

NOTE

The size of the read data, write data, write enable, and address buses are dependent on whether the CTB or DBB interfaces are

used. In the figure above, the first number is for CTR accesses while the second is for DBR accesses (i.e. CTR bus width / DBR bus width).

43.4.4.1 CTR Access

The MIF block allows the HC to directly access the external Channel Table RAM (CTR) when MADR.TB is cleared. Any write to the MADR register triggers a single read or write cycle. Reading from the MADR register does not initiate read/write access.

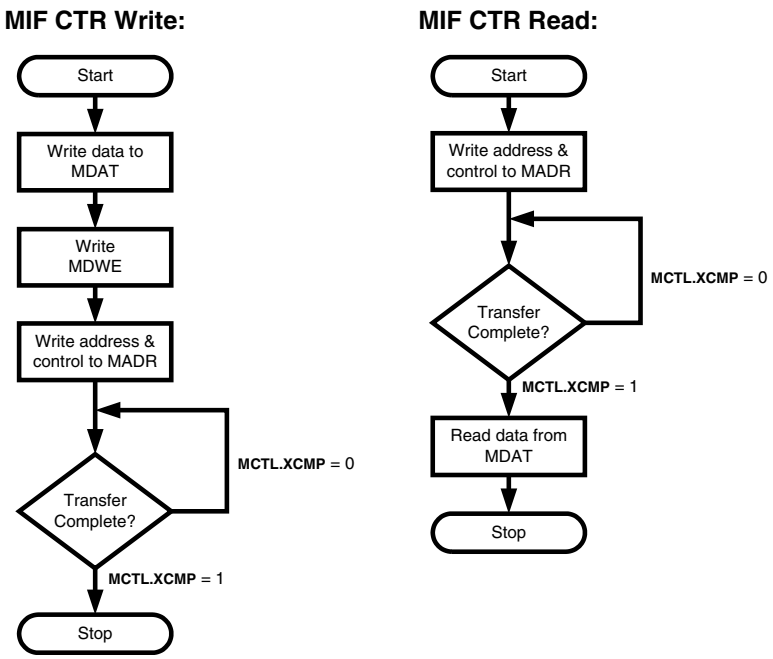

Figure 43-5. MIF CTR Read and Write Flow Diagrams

43.4.4.1.1 Direct CTR Writes

For a direct write of the CTR, the HC first loads the 128-bit data entry into the MDAT0-3 registers. Bitwise write enable control is available via the MDWE0-3 registers.

After the MDATn and MDWEn registers are set up, a write cycle is initiated by writing the address and control information to MADR as follows:

- MADR.WNR = 1
- MADR.TB = 0
- MADR.ADDR[7:0] = 8-bit Target Address

The MIF block sets MCTL.XCMP = 1 to inform the HC when the write is complete.

43.4.4.1.2 Direct CTR Reads

For a direct read of the CTR, the HC initiates a read cycle by writing the address and control information to MADR as follows:

- MADR.WNR = 0
- MADR.TB = 0
- MADR.ADDR[7:0] = 8-bit Target Address

The MIF block sets MCTL.XCMP = 1 to inform the HC when the read is complete. The HC can then read the 128-bit data entry from the MDAT0-3 registers.

43.4.4.1.3 CTR Addressing

The CTR is addressed as a 128-bit wide value. However, the MIF block can only access 32 bits of the addressed CTR data in a single access. Therefore, four 32-bit accesses through the MIF block are required to access a single 128-bit value (e.g. CDT entry).

To access a 16-bit CAT entry in the CTR, only a single access through the MIF is required. For example, to load a CAT61 entry for an isochronous Tx channel with mute and flow control enabled:

- Write MDAT2 = 7B070000h (assumes Connection Label = 7)
- MDWE2 = FFFF0000h (bitwise write enable for 16 msbs; assumes MDWE0/1/3 = 00000000h)
- MADR = 80000087h (write CTR address 87h)

43.4.4.2 DBR Access

The MIF block allows the HC to access the external Data Buffer RAM (DBR) directly when MADR.TB is set. Any write to the MADR register triggers a single read or write cycle. Reading from the MADR register does not initiate read/write access.

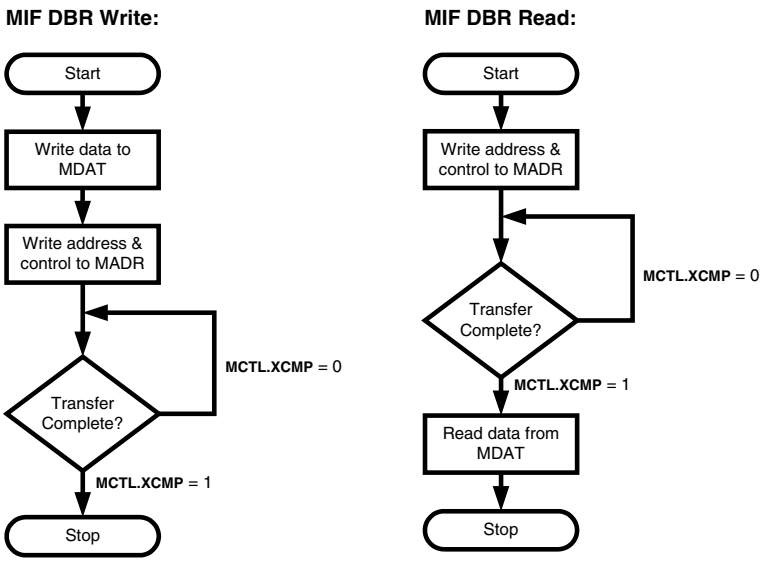

Figure 43-6. MIF DBR Read and Write Flow Diagrams

43.4.4.2.1 Direct DBR Writes

For a direct write of the DBR, the HC first loads the 8-bit data entry into the MDAT0 register at bits[7:0]. MDAT1-3 and MDWE0-3 are not used for DBR access.

After the MDAT0 register is set up, a write cycle is initiated by writing the address and control information to MADR as follows:

- MADR.WNR = 1
- MADR.TB = 1
- MADR.ADDR[13:0] = 14-bit Target Address

The MIF block sets MCTL.XCMP = 1 to inform the HC when the write is complete.

43.4.4.2.2 Direct DBR Reads

For a direct read of the DBR, the HC initiates a read cycle by writing the address and control information to MADR as follows:

- MADR.WNR = 0
- MADR.TB = 1
- MADR.ADDR[13:0] = 14-bit Target Address

The MIF block sets MCTL.XCMP = 1 to inform the HC when the read is complete. The HC can then read the 8-bit data entry from the MDAT0 register at bits[7:0].

43.4.5 Interrupt Interface Block

The Interrupt Interface (INTIF) block performs a low-priority polling algorithm of each of the HBI channel descriptors.

The INTIF alerts the HBI block when specific changes to HBI Channel Descriptors occur.

- For asynchronous and control read/write channels:
  - a packet is available to read in the channel buffer, or
  - sufficient empty space is available in the channel buffer to accept a requested packet write.
- For isochronous read/write channels:
  - the number of valid bytes in the channel buffer exceeds the block size, or
  - the number of empty bytes in the channel buffer exceeds the block size.

43.4.6 AMBA AHB Block

The AMBA AHB block manages data exchange between local channel data buffers within the MLB150 and the system memory buffer.

To support system memory buffering, a ping-pong memory structure is implemented on a per-channel basis using 128-bit descriptors for AHB Descriptor Table (ADT) entries.

NOTE

The 64 ADT entries are directly mapped to the 64 HBI physical channels.

Each logical channel is assigned a separate 128-bit descriptor, defining the data buffers in the system memory used by the DMA interface for that channel. The descriptors are stored at fixed addresses in the external CTR.

43.4.6.1 AHB Descriptor Table

The table below provides an overview of field definitions for ADT entries.

Table 43-15. ADT Field Definitions

Field	No. of Bits	Description	Accessibility
CE	1	Channel enable: 0 = Disabled 1 = Enabled	r,w,u
LE	1	Endianess select: 0 = Big Endian 1 = Little Endian	r,w
PG	1	Page pointer. Software initializes to zero, hardware writes thereafter. 0 = Ping buffer 1 = Pong buffer	r,w,u
RDY1	1	Buffer ready bit for ping buffer page: 0 = Not ready 1 = Ready	r,w
RDY2	1	Buffer ready bit for pong buffer page: 0 = Not ready 1 = Ready	r,w
DNE1	1	Buffer done bit for ping buffer page: 0 = Not done 1 = Done	r,u,c0
DNE2	1	Buffer done bit for pong buffer page: 0 = Not done 1 = Done	r,u,c0
ERR1	1	AHB error response detected for ping buffer page: 0 = No error 1 = Rrror	r,u,c0
ERR2	1	AHB error response detected for pong buffer page: 0 = No error 1 = Error	r,u,c0
PS1	1	Packet start bit for ping buffer page: 0 = No packet start 1 = Packet start Reserved for synchronous and isochronous channels.	r,w,u (both Tx and Rx)
PS2	1	Packet start bit for pong buffer page: 0 = No packet start 1 = Packet start Reserved for synchronous and isochronous channels.	r,w,u (both Tx and Rx)
MEP1	1	Most Ethernet Packet (MEP) indicator for ping buffer page: 0 = Not MEP 1 = MEP MEP1 only valid for the first page of a segmented buffer. Reserved for control, synchronous and isochronous channels.	Rsvd for Tx r,u,c0 for Rx
MEP2	1	MEP packet indicator for pong buffer page: 0 = not MEP 1 = MEP MEP2 only valid for the first page of a segmented buffer. Reserved for control, synchronous and isochronous channels.	Rsvd for Tx r,u,c0 for Rx
BD1*	11 to 13	Buffer depth for ping buffer page: 11 or 12-bits for asynchronous and control channels. 13-bits for synchronous and isochronous channels.	r,w
BD2*	11 to 13	Buffer depth for pong buffer page: 11 or 12-bits for asynchronous and control channels. 13-bits for synchronous and isochronous channels.	r,w
BA1	32	Buffer base address for ping buffer page	r,w
BA2	32	Buffer base address for pong buffer page	r,w
Reserved	varies	Software writes a zero to all *Reserved* bits when the entry is initialized. The *Reserved* bits are *Read-only* after initialization.	r,w,u
* The buffer depth (BD1 and BD2) for synchronous channels must consider if *Multi-Frame per Sub-buffer* mode is enabled.			

Data exchange across the AHB interface can be configured as Little Endian (LE = 1) or Big Endian (LE = 0). The figure below provides an overview of the endian options, chosen by an ADT descriptor field.

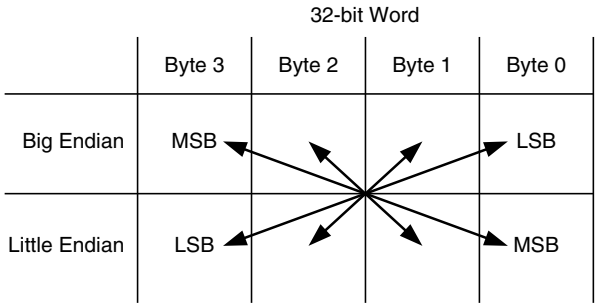

Figure 43-7. Endianness Overview

The figure below shows an example of the ping-pong system memory structure. This system memory structure is similar for all channel types and shows the relationship between the BAn, BDn, and PG descriptor fields.

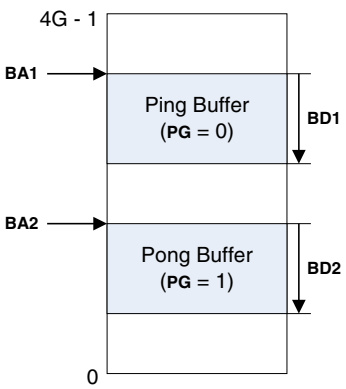

Figure 43-8. Ping-Pong System Memory Structure

Each ADT entry holds a 32-bit BAn field which defines the start of each ping or pong buffer within system memory. The BDn field is used to indicate the size for the respective ping or pong page. The maximum size is 2k-entries for asynchronous and control channels; 8k-entries for isochronous and synchronous channels.

43.4.6.2 AHB Synchronous Channel Descriptors

The table below shows the format for a synchronous ADT entry. The field definitions are defined in Table 43-15. Each synchronous channel buffer can be up to 8k-bytes deep.

Table 43-16. Synchronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															

Table continues on the next page...

32	RDY 1	DNE 1	ERR 1	BD1[12:0]												
48	RDY 2	DNE 2	ERR 2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

43.4.6.3 AHB Isochronous Channel Descriptors

The isochronous buffering scheme allows each ping or pong buffer to contain a single block or a multiple number of blocks. For this reason, the isochronous buffer depth (BDn) must be defined in terms of an *integer number* (n) and *block size* (BS) (e.g. BDn = n x (BS + 1) - 1).

Table 43-17 shows the format for an isochronous ADT entry. The field definitions are defined in Table 43-15. Each isochronous channel buffer can be up to 8k-bytes deep.

Table 43-17. Isochronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	BD1[12:0]												
48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

43.4.6.4 AHB Asynchronous and Control Channel Descriptors

Every asynchronous and control packet adheres to the Port Message Protocol (PMP), which designates the first two bytes of each packet as the packet length (PML). Each packet must be no more than 2048 bytes.

Software must set the buffer ready bit (RDYn) for each buffer as it programs the DMA. As hardware processes each buffer, it sets the done bit (DNEn) and generates an interrupt to inform HC. When hardware finishes processing a buffer it can begin processing another buffer if RDYn is set. The application is responsible for setting up and configuring the channel buffer descriptor prior to every DMA access on the channel.

Two packet modes are supported by hardware for programming the DMA, single-packet mode and multiple-packet mode.

43.4.6.4.1 Single-packet Mode

The single-packet mode asynchronous and control buffering scheme supports a maximum of one packet per buffer (e.g. ping or pong). Both non-segmented and segmented data packets are allowed while using single-packet mode.

Non-segmented packets are exchanged when only one buffer (e.g. ping or pong) is needed for packet transfer. Segmented packets are exchanged when a single packet is too long for one buffer and the packet must span multiple buffers. The figure below shows the memory space usage for both non-segmented and segmented asynchronous or control packets along with the packet start bit (PSn). While using single-packet mode, buffer done (DNEn) is set in hardware when a packet is done or the buffer is full.

Table 43-18 shows the format for single-packet mode asynchronous and control ADT entries. The field definitions are defined in Table 43-15.

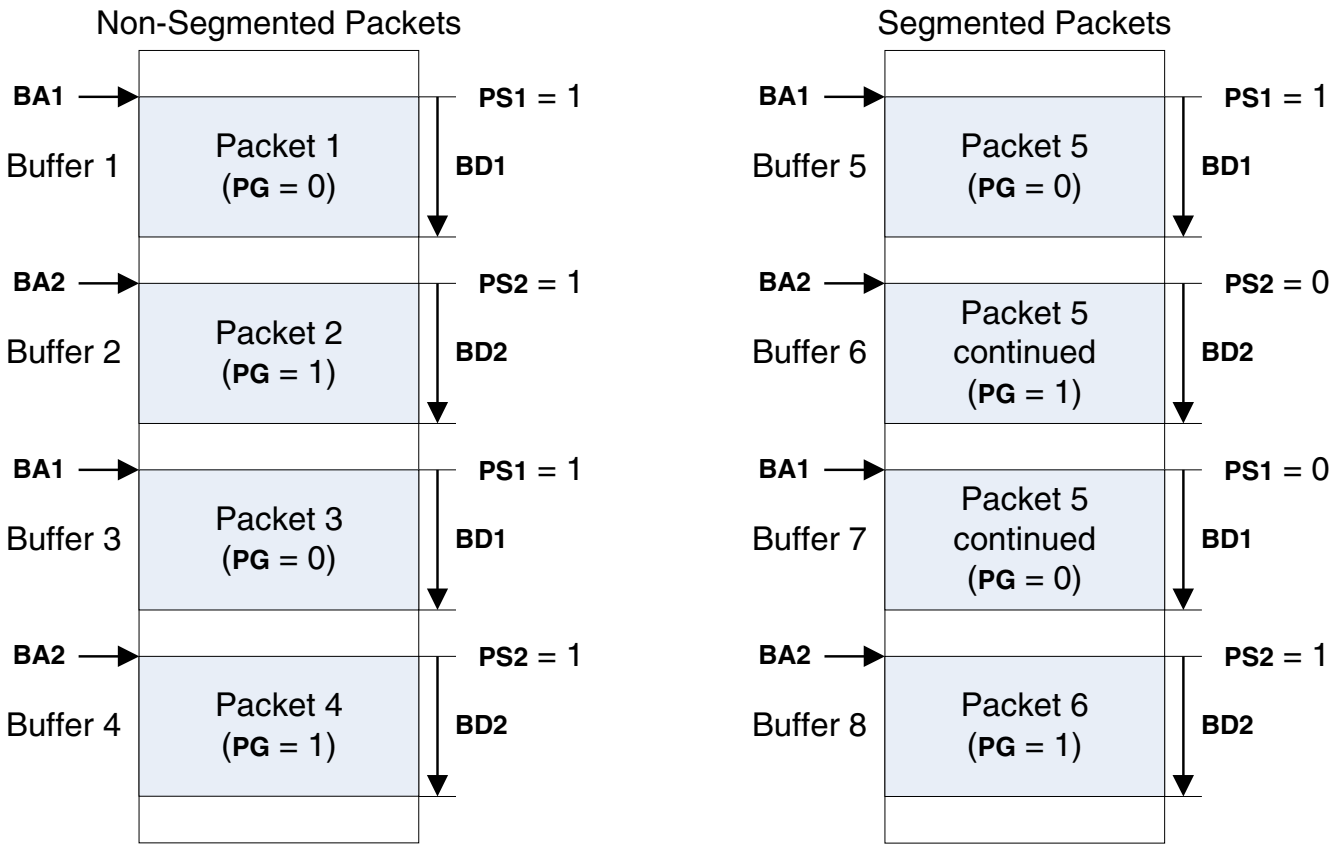

Figure 43-9. Single-packet Asynchronous or Control System Memory Structure

Table 43-18. Single-packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	MEP1	BD1[10:0]										
48	RDY2	DNE2	ERR2	PS2	MEP2	BD2[10:0]										
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

43.4.6.4.2 Multiple-packet Mode

The multiple-packet mode asynchronous and control buffering scheme supports more than one packet per system memory buffer, as shown in the figure below. Multiple-packet mode reduces the interrupt rate for packet channels at the cost of increasing buffering and latency.

For Tx packet channels in multiple-packet mode, software sets the packet start bit (PSn) for every buffer. Setting PSn informs hardware that the first two bytes of the buffer contains the port message length (PML) of the first packet. After the first packet, hardware keeps track of where packets start and end within the current buffer. Software should not write to PSn while the buffer is active (RDYn = 1 and DNEn = 0). For Tx packet channels, the buffer is done (DNEn= 1) when the last byte of the last packet in the buffer is read from system memory. Software should set the buffer depth to contain the exact number of complete packets for that buffer. Segmented buffers are not supported for Tx packet channels in multiple-packet mode.

For Rx packet channels in multiple-packet mode, PSn has no meaning and should be ignored. Software is responsible for keeping track of where each packet starts and ends within the multiple-packet buffer via the packet PML. The buffer done bit (DNEn) is set in hardware for Rx channels when a buffer is full (see Buffer 1 in the figure below) or if a packet ends exactly 1-byte before the end of the buffer (see Buffer 2 in the figure below). Multiple-packet mode also supports segmented Rx packets spanning two or more buffers (see Buffers 3 - 6in the figure below).

Table 43-19 shows the format for multiple-packet mode asynchronous and control ADT entries. The field definitions are defined in Table 43-15.

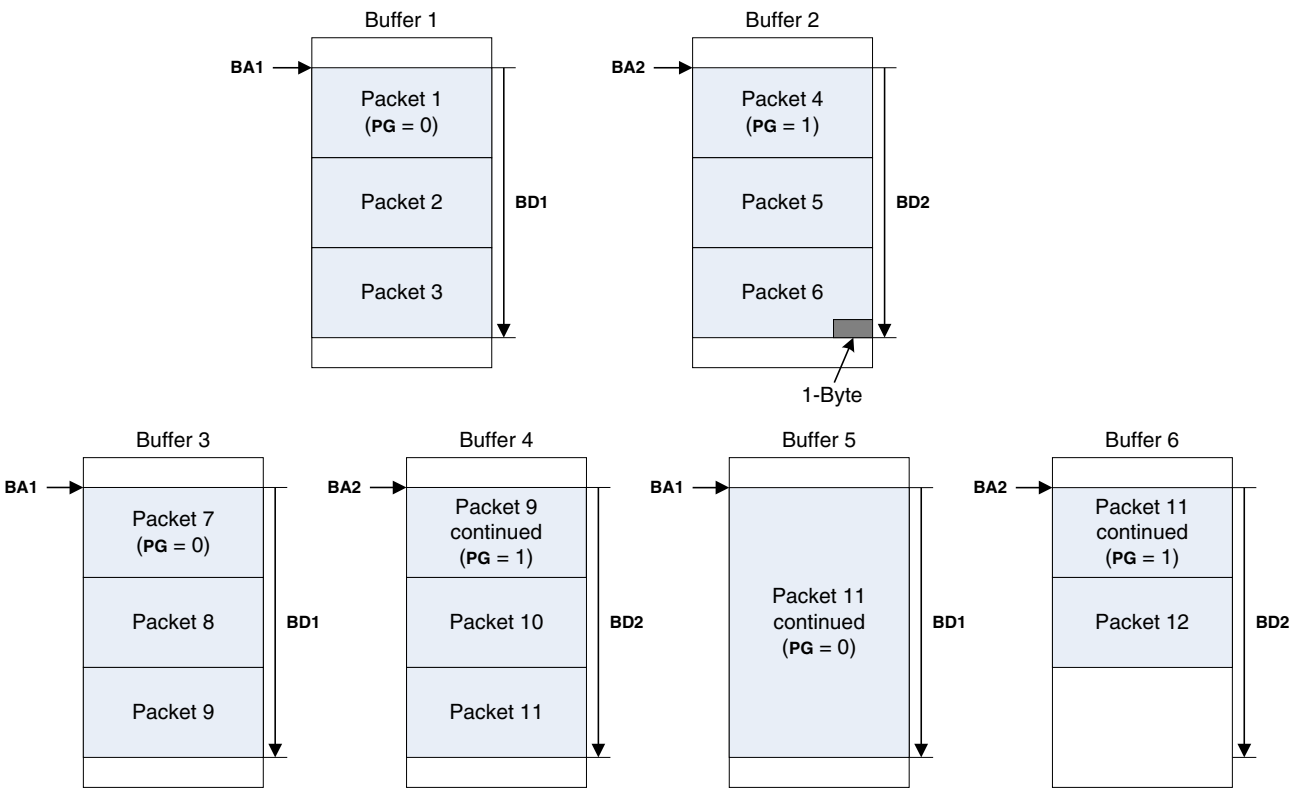

Figure 43-10. Multiple-packet Asynchronous or Control System Memory Structure

Table 43-19. Multiple-packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1*	BD1[11:0]											
48	RDY2	DNE2	ERR2	PS2*	BD2[11:0]											
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															
* PSn is only valid for TX channels. Set PSn = 1 at the start of the buffer.																

43.5 Software Flow

The top-level software tasks the application must perform can be placed in two categories.

- Channel Initialization
- Channel Servicing

43.5.1 Channel Initialization

The software flow required to initialize a channel must be performed in order to ensure proper operation.

For clarity, the software flow is grouped as follows:

- Configure the Hardware
- Program the Routing Fabric Block
- Program the AMBA AHB Block DMAs
- Synchronize and Unmute Synchronous Channel

43.5.1.1 Configure the Hardware

The MLBC0, HMCR0, HMCR1 and HCTL registers are accessible directly via APB reads and writes.

1. Initialize CTR and registers

a. Set all bit of the CTR (CAT, CDT, and ADT) to'0'.
b. Set all bits of all registers to'0'.

2. Configure the MediaLB interface
   a. Select 3-pin or 6-pin MediaLB operation: MLBC0.MLBPEN = 0 (3-pin), MLBC0.MLBPEN = 1 (6-pin)
   b. Select MediaLB clock speed via MLBC0.MLBCLK
   c. Set MediaLB enable via MLBC0.MLBEN
3. Configure the HBI interface
   a. Set HMCR0 and HMCR1 = FFFFFFFFh to activate all channels
   b. Set the HBI enable bit: HCTL.EN = 1

43.5.1.2 Program the Routing Fabric Block

The CAT and CDT reside in the external CTR and are programmed indirectly via APB or I/O reads and writes to the MIF block.

1. Initialize all bits of the CAT to '0'
2. Select a logical channel: N = 0 - 63
3. Program the CDT for channel N
   a. Set the 14-bit base address (BA)
   b. Set the 12-bit or 13-bit buffer depth (BD): BD = buffer depth in bytes -1
      - i. For synchronous channels: (BD + 1) = 4 x frames per sub-buffer (m) x bytes-per-frame (bpf)
      - ii. For isochronous channels: (BD + 1) mod (BS + 1) = 0
      - iii. For asynchronous channels: (BD + 1) >= max packet length (1024 for a MOST Data Packet (MDP); 1536 for a MOST Ethernet Packet (MEP))
      - iv. For control channels: (BD + 1) >= max packet length (64)
   c. For isochronous channels, set the block size (BS): BS = block size in bytes - 1
   d. Set all other bits of the CDT to '0'
4. Program the CAT for the inbound DMA
   a. For Tx channels (to MediaLB) HBI is the inbound DMA
   b. For Rx channels (from MediaLB) MediaLB is the inbound DMA
   c. Set the channel direction: RNW = 0
   d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
   e. Set the connection label: CL[5:0] = N
   f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1).
   g. Set the channel enable: CE = 1
   h. Set all other bits of the CAT to '0'
5. Program the CAT for the outbound DMA
   a. For Tx channels (to MediaLB) MediaLB is the outbound DMA

b. For Rx channels (from MediaLB) HBI is the outbound DMA
c. Set the channel direction: RNW = 1
d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
e. Set the channel label: CL[5:0] = N
f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
g. Set the channel enable: CE = 1
h. Set all other bits of the CAT to '0'

6. Repeat steps 2-5 to initialize all logical channels

43.5.1.3 Program the AMBA AHB Block DMAs

The ADT resides in the external CTR and is programmed indirectly via APB reads and writes to the MIF.

1. Initialize all bits of the ADT to '0'
2. Select a logical channel: N = 0 - 63
3. Program the AMBA AHB block ping page for channel N
   a. Set the 32-bit base address (BA1)
   b. Set the 11-bit buffer depth (BD1): BD1 = buffer depth in bytes - 1
      - i. For synchronous channels: (BD1 + 1) = n x frames per sub-buffer (m) x bytes-per-frame (bpf)
      - ii. For isochronous channels: (BD1 + 1) mod (BS + 1) = 0
      - iii. For asynchronous channels: 5 <= (BD1 + 1) <= 4096 (max packet length)
      - iv. For control channels: 5 <= (BD1 + 1) <= 4096 (max packet length)
   c. For asynchronous and control Tx channels set the packet start bit (PS1) iff the page contains the start of the packet
   d. Clear the page done bit (DNE1)
   e. Clear the error bit (ERR1)
   f. Set the page ready bit (RDY1)
4. Program the AMBA AHB block pong page for channel N
   a. Set the 32-bit base address (BA2)
   b. Set the 11-bit buffer depth (BD2): BD2 = buffer depth in bytes - 1
      - i. For synchronous channels: (BD2 +1) = n x frames per sub-buffer (m) x bytes-per-frame (bpf)
      - ii. For isochronous channels: (BD2 + 1) mod (BS + 1) = 0
      - iii. For asynchronous channels: 5 <= (BD2 + 1) <= 4096 (max packet length)
      - iv. For control channels: 5 <= (BD2 + 1) <= 4096 (max packet length)

c. For asynchronous and control Tx channels set the packet start bit (PS2) if the page contains the start of the packet
d. Clear the page done bit (DNE2)
e. Clear the error bit (ERR2)
f. Set the page ready bit (RDY2)

5. Select Big Endian (LE = 0) or Little Endian (LE = 1)
6. Select the active page: PG = 0 (ping), PG = 1 (pong)
7. Set the channel enable (CE) bit for all active logical channels
8. Repeat steps 2-7 for all active logical channels

NOTE

All asynchronous and control packets must start with a PMP header. The first two bytes of the PMP header contains the Port Message Length (PML), which defines the length of the message that follows in bytes (not including PML itself). Hardware uses the PML to determine when a packet is complete. Asynchronous and control packets can also be segmented into two or more pages as well as contain multiple packets per page within system memory.

43.5.1.4 Synchronize and Unmute Synchronous Channel

The MLBC0 and MLBC1 registers are accessible directly via APB reads and writes.

1. Check that MediaLB clock is running (MLBC1.CLKM = 0)
2. If MLBC1.CLKM = 1, clear the register bit, wait one APB or I/O clock cycle and repeat step 1.
3. Poll for MediaLB lock (MLBC0.MLBLK = 1)
4. Wait four frames
5. Unmute synchronous channel(s)

43.5.2 Channel Servicing

After initialization, each channel will require periodic servicing.

The following software flows can be performed concurrently and in any order:

- Servicing the AMBA AHB Block (DMA) Interrupts
- Servicing the MediaLB Interrupts
- Polling for MediaLB System Commands

43.5.2.1 Servicing the AMBA AHB Block (DMA) Interrupts

The ACMR0, ACMR1, ACTL, ACSR0, and ACSR1 registers are accessible directly via APB reads and writes.

1. Program the ACMRn registers to enable interrupts from all active DMA channels
2. Select the status clear method: SCTL.SCE = 0 (hardware clears on read), SCTL.SCE = 1 (software writes a '1' to clear)
3. Select 1 or 2 interrupt signals: SCTL.SMX = 0 (one interrupt for channels 0-31 on *ahb_int[0]* and another interrupt for channels 32-63 on *ahb_int[1]*), SCTL.SMX = 1 (single interrupt for all channels on *ahb_int[0]*)
4. Wait for an interrupt from *ahb_int[1:0]*
5. Read the ACSRn registers to determine which channel or channels are causing the interrupt
6. If SCTL.SCE = 1, write the results of step 5 back to ACSR0 and ACSR1 to clear the interrupt
7. Select a logical channel (N = 0-63) with an interrupt to service
8. Read the ADT entry for channel N
   a. Determine the active page (ping or pong) via the PG bit
   b. Determine which page(s) are done via the DNEn bits
   c. Determine which channels encountered an AHB error via the ERRn bit
   d. Determine which asynchronous and control Rx channel pages contain a packet start via the PSn bit (extract the PML)
9. Reprogram the expired or broken AHB page(s) via steps 3 and 4 in Program the AMBA AHB Block DMAs,
10. Repeat steps 6-9 for all channels with pending interrupts
11. Repeat steps 4-10 while there are active channels

NOTE

Channels that receive an AHB error response are disabled (CE = 0) by hardware.

43.5.2.2 Servicing the MediaLB Interrupts

1. Select the MediaLB Channel Status Register (MSn) to be cleared by software, writing a '0' to the appropriate bits
2. Program MIEN to enable protocol error interrupts for all active MediaLB channels (MIEN.CTX_PE = 1, MIEN.CRX_PE = 1, MIEN.ATX_PE = 1, MIEN.ARX_PE = 1, MIEN.SYNC_PE = 1, and MIEN.ISOC_PE = 1)
3. Wait for an interrupt on the *mlb_int* signal.
4. Read the MSn registers to determine which channel(s) are causing the interrupt

5. Read RSTS/WSTS of the appropriate CDT(s) to determine the interrupt type
6. Clear RSTS/WSTS errors to resume channel operation
    a. For synchronous channels: WSTS[3] = 0
    b. For isochronous channels: WSTS[2:1] = 00
    c. For asynchronous and control channels: RSTS[4]/WSTS[4] = 0 and RSTS[2]/WSTS[2] = 0

43.5.2.3 Polling for MediaLB System Commands

The MLB supports the MediaLB System Commands (e.g. MlbScan, MlbReset, MOST_Unlock). The MediaLB System Status (MSS) Register is used to detect a System Command received from the MediaLB Controller. The MLB automatically sends the appropriate system response to the MediaLB Controller.

The procedure for the application is:

1. The application periodically polls the MSS register.
2. Clear by writing a '0' to the appropriate bit in MSS register after the application finishes the service.
3. If MSS.SWSYSCMD = 1, read the MSD register to receive the system data sent from MediaLB Controller.

43.5.3 Low Power Mode

MLB doesn't provide dedicated low power mode features.

In case the clocks of digital IP need to shut down to save power, the following operations are recommended before entering low power mode:

- Finish any active MLB transfer
- Disable MLB (clear the MLBEN and MLBPEN bits in MLBC0)
- Disable HBI (clear all bits in HCMR0 and HCMR1, clear EN bit in HCTL)
- Mask AHB interrupts (clear all bits in ACMR0 and ACMR1)

For information on configuring the MLB IP if the clocks are re-enabled, see Configure the Hardware.

43.6 MLB150 Memory Map/Register Definition

The MLB150 registers are divided into 4 sections.

The first section begins at offset 0h00 and describes the MediaLB block registers.

The second section begins at offset 0h80 and it shows the address mapping of the Internal HBI Registers.

The third set begins at offset 0hC0 and implements ten 32-bit I/O registers for CTR transfers, including: data registers (MDATn), write enable registers (MDWEn), a control register (MCTL), and an address register (MADR).

The fourth set, the AMBA AHB registers, begins at offset 0h3C0. They consist of:

- one 32-bit register for control
- two 32-bit registers for interrupt status
- two 32-bit registers for channel interrupt masks

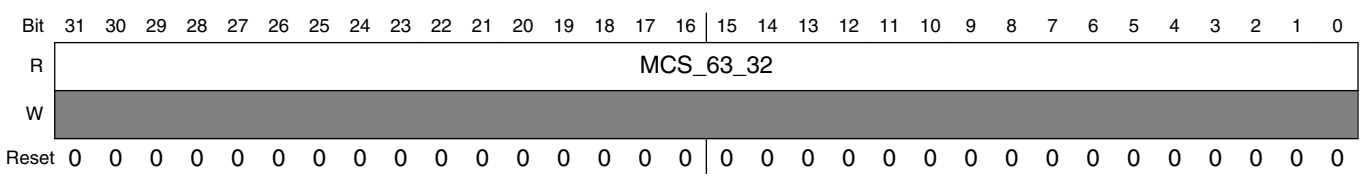
2–1 SDRTO	MLB 6-pin interface: Signal/Data receiver threshold offset control.
0 SDOPC	MLB 3-pin interface: Signal/Data output phase control. 0 MLB_SIG / MLB_DATA launch at rising edge of MLB_CLK(default) 1 MLB_SIG / MLB_DATA launch at falling edge of MLB_CLK

43.6.5 MediaLB Channel Status1 Register (MLB_MS1)

Address: 218_C000h base + 14h offset = 218_C014h

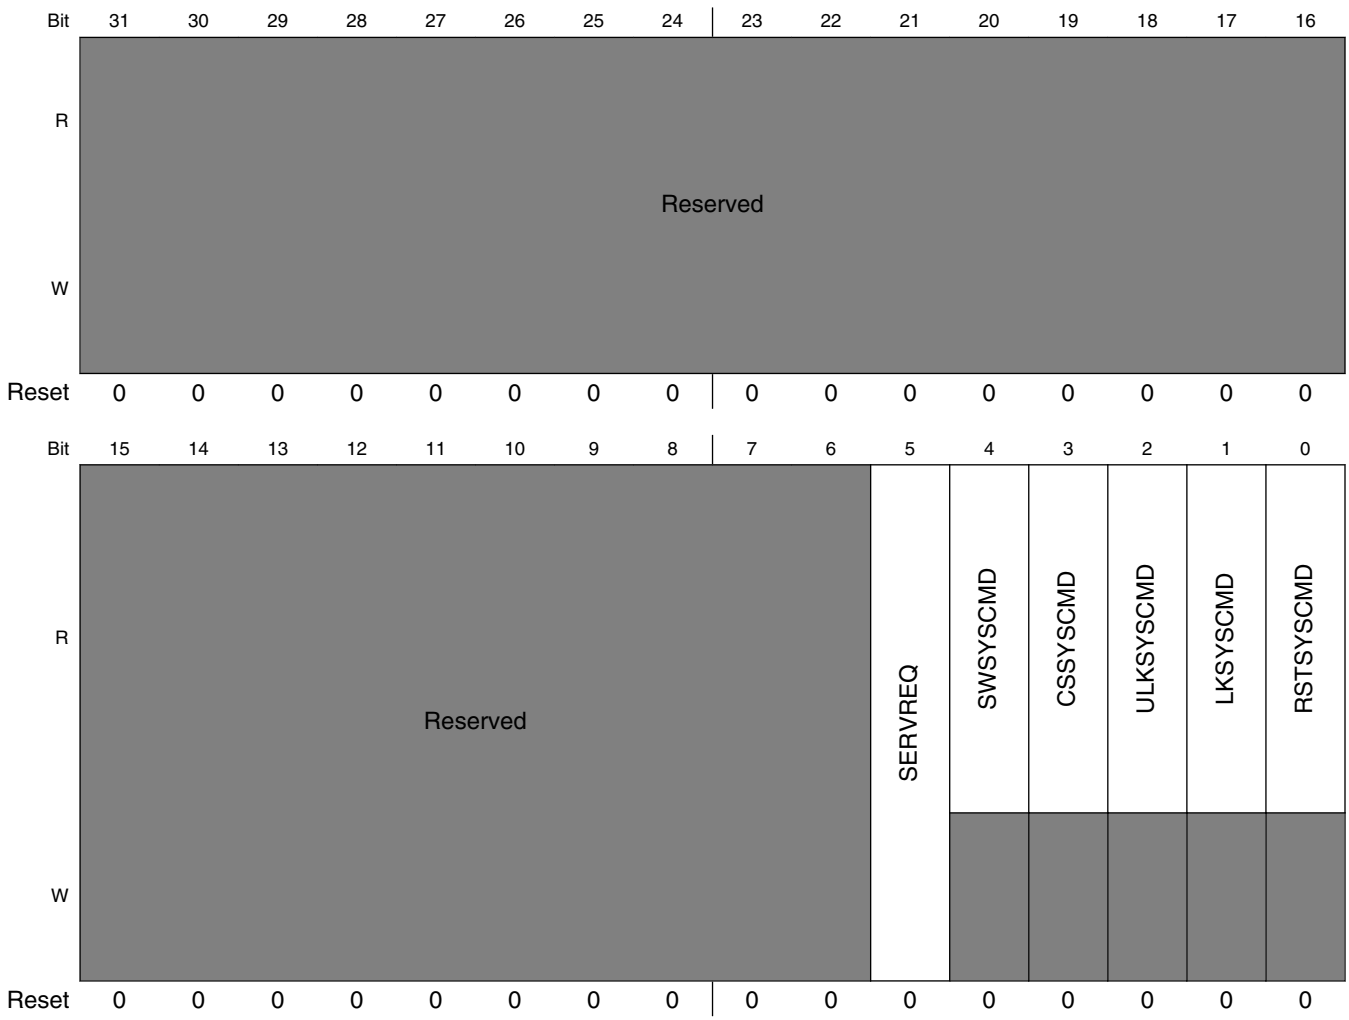


MLB_MS1 field descriptions

Field	Description
MCS_63_32	MediaLB channel status. Indicates the channel status for MediaLB channels 63 to 32. Channel status bits are set by hardware and cleared by software. Status is only set if the appropriate bits in the MIEN register are set.

43.6.6 MediaLB System Status Register (MLB_MSS)

Address: 218_C000h base + 20h offset = 218_C020h



MLB_MSS field descriptions

Field	Description
31–6 -	This field is reserved. Reserved
5 SERVREQ	Service request enabled. When set, the MediaLB block responds with a "device present, request service" system response if a matching channel scan system command is detected. When cleared, the MediaLB block responds with a "device present" system response.
4 SWSYSCMD	Software system command detected (in the system quadlet). Set by hardware, cleared by software. Data is stored in the MSD register for this command.
3 CSSYSCMD	Channel scan system command detected (in the system quadlet). Set by hardware, cleared by software. If the node address specified in *Data* quadlet matches the value in **MLBC1.NDA**, the device responds either "device present" or "device present, request service" system response in the next system quadlet.

Table continues on the next page...

MLB_MSS field descriptions (continued)

Field	Description
2 ULKSYSCMD	Network unlock system command detected (in the system quadlet). Set by hardware, cleared by software.
1 LKSYSCMD	Network lock system command detected (in the system quadlet). Set by hardware, cleared by software.
0 RSTSYSCMD	Reset system command detected (in the system quadlet). Set by hardware, cleared by software.

43.6.7 MediaLB System Data Register (MLB_MSD)

Address: 218_C000h base + 24h offset = 218_C024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

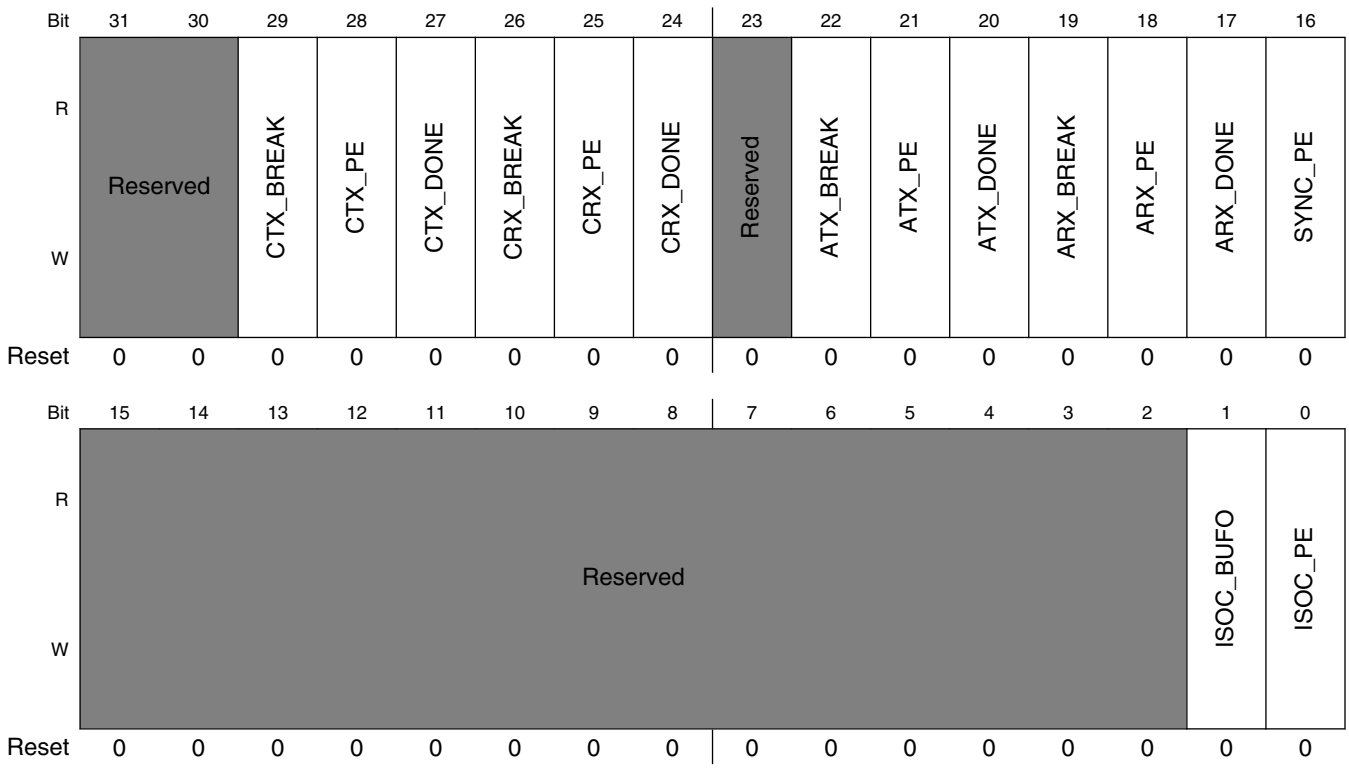
MLB_MSD field descriptions

Field	Description
31–24 SD3_7_0	System data (byte 3). Updated with MediaLB Data[31:24] when a MediaLB software system command is received in the system quadlet. If MSS.SWSYSCMD is already set, then SD3 is not updated. (read-only)
23–16 SD2_7_0	System data (byte 2). Updated with MediaLB Data[23:16] when a MediaLB software system command is received in the system quadlet. If MSS.SWSYSCMD is already set, then SD2 is not updated. (read-only)
15–8 SD1_7_0	System data (byte 1). Updated with MediaLB Data[15:8] when a MediaLB software system command is received in the system quadlet. If MSS.SWSYSCMD is already set, then SD1 is not updated. (read-only)
SD0_7_0	System data (byte 0). Updated with MediaLB Data[7:0] when a MediaLB software system command is received in the system quadlet. If MSS.SWSYSCMD is already set, then SD0 is not updated. (read-only)

43.6.8 MediaLB Interrupt Enable Register (MLB_MIEN)

Address: 218_C000h base + 2Ch offset = 218_C02Ch



MLB_MIEN field descriptions

Field	Description
31–30 -	This field is reserved. Reserved
29 CTX_BREAK	Control Tx break enable. When set, a *ReceiverBreak* response received from the receiver on a control Tx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
28 CTX_PE	Control Tx protocol error enable. When set, a *ProtocolError* generated by the receiver on a control Tx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
27 CTX_DONE	Control Tx packet done enable. When set, a packet transmitted with no errors on a control Tx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
26 CRX_BREAK	Control Rx break enable. When set, a *ControlBreak* command received from the transmitter on a control Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
25 CRX_PE	Control Rx protocol error enable. When set, a *ProtocolError* detected on a control Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
24 CRX_DONE	Control Rx packet done enable. When set, a packet received with no errors on a control Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
23 -	This field is reserved. Reserved
22 ATX_BREAK	Asynchronous Tx break enable. When set, a *ReceiverBreak* response received from the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.

Table continues on the next page...

MLB_MIEN field descriptions (continued)

Field	Description
21 ATX_PE	Asynchronous Tx protocol error enable. When set, a *ProtocolError* generated by the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
20 ATX_DONE	Asynchronous Tx packet done enable. When set, a packet transmitted with no errors on an asynchronous Tx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
19 ARX_BREAK	Asynchronous Rx break enable. When set, a *AsyncBreak* command received from the transmitter on an asynchronous Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
18 ARX_PE	Asynchronous Rx protocol error enable. When set, a *ProtocolError* detected on an asynchronous Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
17 ARX_DONE	Asynchronous Rx done enable. When set, a packet received with no errors on an asynchronous Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
16 SYNC_PE	Synchronous protocol error enable. When set, a *ProtocolError* detected on a synchronous Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.
15–2 -	This field is reserved. Reserved
1 ISOC_BUFO	Isochronous Rx buffer overflow enable. When set, a buffer overflow on an isochronous Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set. This occurs only when isochronous flow control is disabled.
0 ISOC_PE	Isochronous Rx protocol error enable. When set, a *ProtocolError* detected on an isochronous Rx channel causes the appropriate channel bit in the MS0 or MS1 registers to be set.

43.6.9 MediaLB 6-pin Control 1 Register (MLB_MLBPC1)

Address: 218_C000h base + 38h offset = 218_C038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

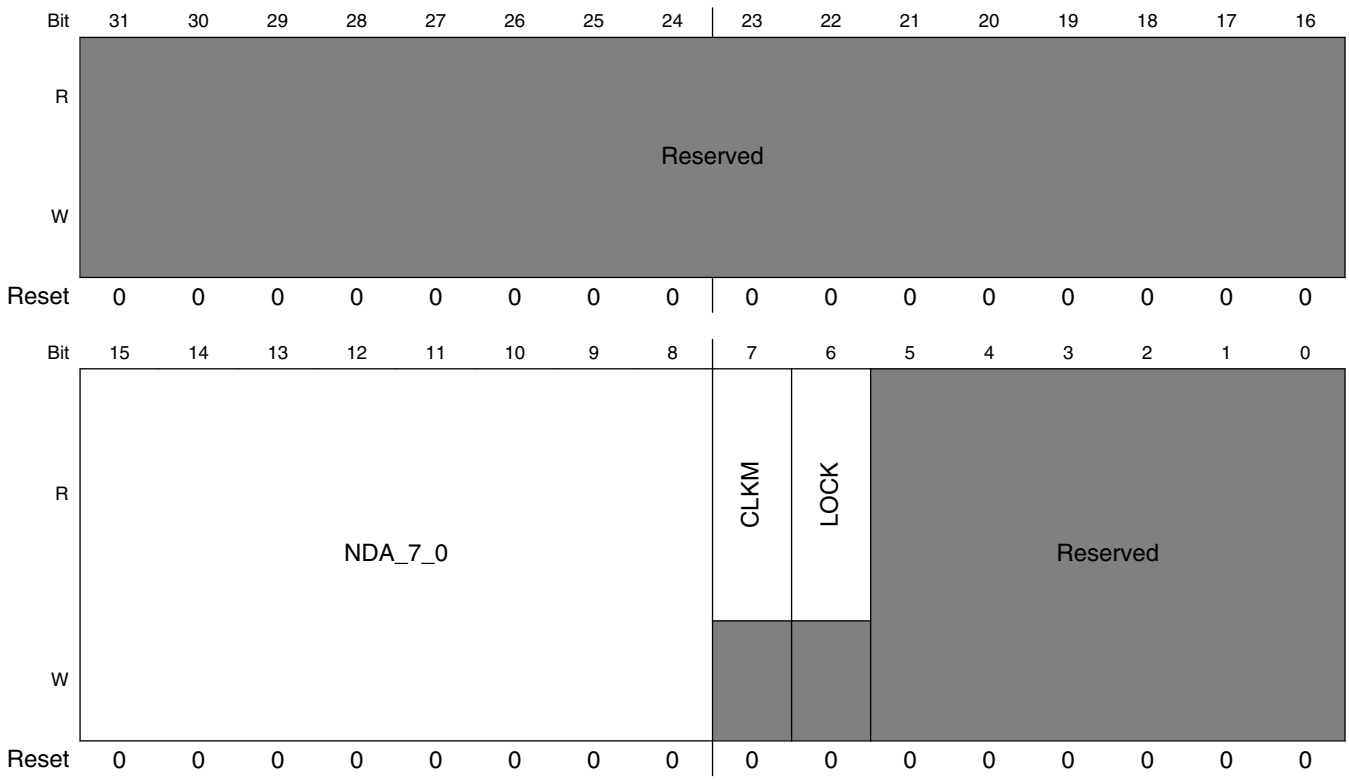
MLB_MLBPC1 field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11–8 CKRCVBIAS_3_0	Clock receiver bias control (for MediaLB 6-pin interface). Must be written to 0xC when MediaLB 6-pin is initialized (final value needs to be determined through characterization). This value is driven on MLB_CLK, MLB_CLK_N and MLB_CLK_P output pins and has no internal function.
7–4 SDXMTBIAS_3_0	Signal/Data transmitter bias control (for MediaLB 6-pin interface). Must be written to 0xC when MediaLB 6-pin is initialized (final value needs to be determined through characterization). This value is driven on MLB_DATA, MLB_DATA_N and MLB_DATA_P output pins and has no internal function.
SDRCVBIAS_3_0	Signal/Data receiver bias control (for MediaLB 6-pin interface). Must be written to 0xC when MediaLB 6-pin is initialized (final value needs to be determined through characterization). This value is driven on MLB_SIG, MLB_SIG_N and MLB_SIG_P output pins and has no internal function.

43.6.10 MediaLB Control 1 Register (MLB_MLBC1)

Address: 218_C000h base + 3Ch offset = 218_C03Ch



MLB_MLBC1 field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 NDA_7_0	Node device address. Used for system commands directed to individual MediaLB nodes.
7 CLKM	MediaLB clock missing status. Set when MLB_CLK (MediaLB clock) is not toggling at the pin; cleared by software.
6 LOCK	MediaLB lock error status. Set when MediaLB is unlocked; cleared by software.
-	This field is reserved. Reserved

43.6.11 HBI Control Register (MLB_HCTL)

The HC can control and monitor general operation of the HBI block by reading and writing the HBI Control Register (HCTL) through the I/O interface. Each bit of HCTL is read/write.

Address: 218_C000h base + 80h offset = 218_C080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
CERR_63_32	Bitwise channel error bit

43.6.16 HBI Channel Busy 0 Register (MLB_HCBR0)

The HC can determine which channel(s) are busy by reading the HBI Channel Busy Registers (HCBRn). An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table (Table 43-5), and
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of HCBRn is read-only.

Address: 218_C000h base + 98h offset = 218_C098h

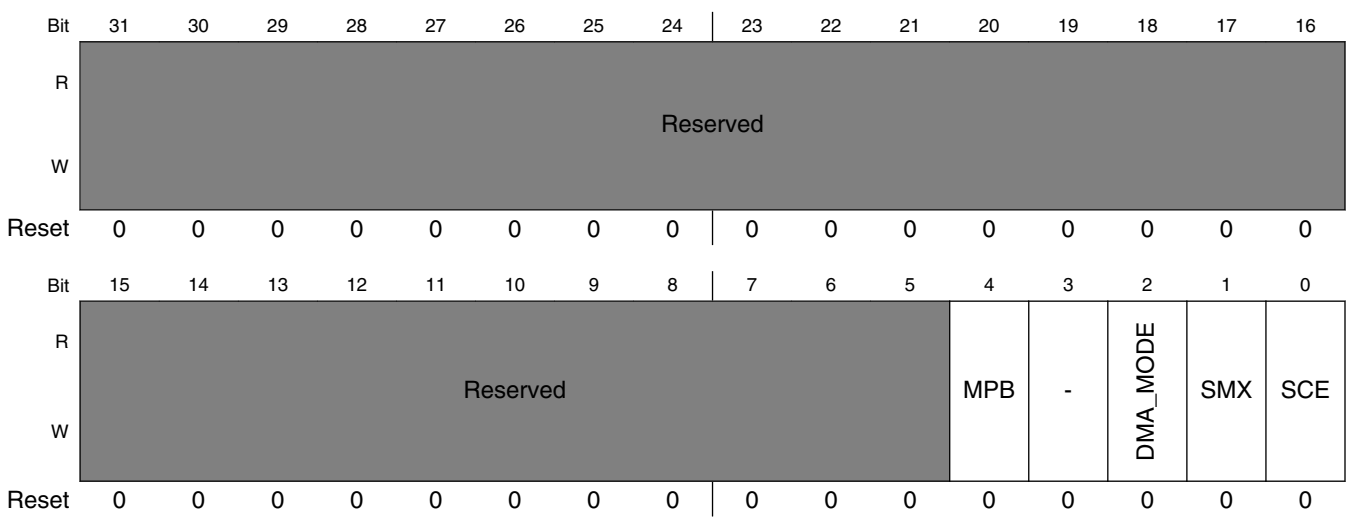
43.6.28 AHB Control Register (MLB_ACTL)

The AHB Control (ACTL) register is written by the HC to configure the AMBA AHB block for channel interrupts. ACTL contains three configuration fields, one is used to select the DMA mode, one is used to mux channel interrupts onto a single interrupt signal, and the last selects the method of clearing channel interrupts (either software or hardware).

Address: 218_C000h base + 3C0h offset = 218_C3C0h



MLB_ACTL field descriptions

Field	Description
31–5 -	This field is reserved. Reserved

3 -	Reserved.
2 DMA_MODE	DMA Mode: 0 DMA Mode 0 1 DMA Mode 1
1 SMX	AHB interrupt mux enable: 0 ACSR0 generates an interrupt on *ahb_int[0]*; ACSR1 generates an interrupt on *ahb_int[1]* 1 ACSR0 and ACSR1 generate an interrupts on *ahb_int[0]* only
0 SCE	Software clear enable: 0 Hardware clears interrupt after a ACSRn register read 1 Software clears interrupt

43.6.29 AHB Channel Status 0 Register (MLB_ACSR0)

The AHB Channel Status (ACSRn) registers contain interrupt bits for each of the 64 physical channels. When an ACSRn register bit is set, it indicates that the corresponding physical channel has an interrupt pending.

An AHB interrupt is triggered when either DNEn or ERRn is set within the AHB Channel Descriptor. The HC is notified of the channel interrupt via *ahb_int[1:0]*. When an interrupt occurs in ACSR0 (for channels 31 to 0) *ahb_int[0]* is set. When an interrupt occurs in ACSR1 (for channels 63 to 32) *ahb_int[1]* is set.

Interrupts in ACSR0 and ACSR1 can be optionally muxed onto a single interrupt signal, *ahb_int[0]*, if ACTL.SMX = 1. If ACTL.SCE = 0, hardware automatically clears the interrupt bit(s) after the HC reads the ACSRn register. Alternatively, if ACTL.SCE = 1, software must write a 1 to the appropriate bit(s) of ACSRn to clear the interrupt(s).

Address: 218_C000h base + 3D0h offset = 218_C3D0h

CHS[63:32]	Interrupt status for logical channels 63 to 32: 0 None 1 Interrupt

43.6.31 AHB Channel Mask 0 Register (MLB_ACMR0)

Using the AHB Channel Mask (ACMRn) register, the HC can control which channel(s) generate interrupts on *ahb_int[1:0]*. All ACMRn register bits default as '0' ("masked"); therefore, the HC must initially write ACMRn to enable interrupts. Each bit of ACMRn is read/write accessible.

Address: 218_C000h base + 3D8h offset = 218_C3D8h

Chapter 44
Multi Mode DDR Controller (MMDC)

44.1 Overview

MMDC is a multi-mode DDR controller that supports DDR3/DDR3L x16/x32/x64 and LPDDR2 two channel x16/x32 memory types. MMDC is configurable, high performance, and optimized.

The following figure shows the MMDC block diagram.

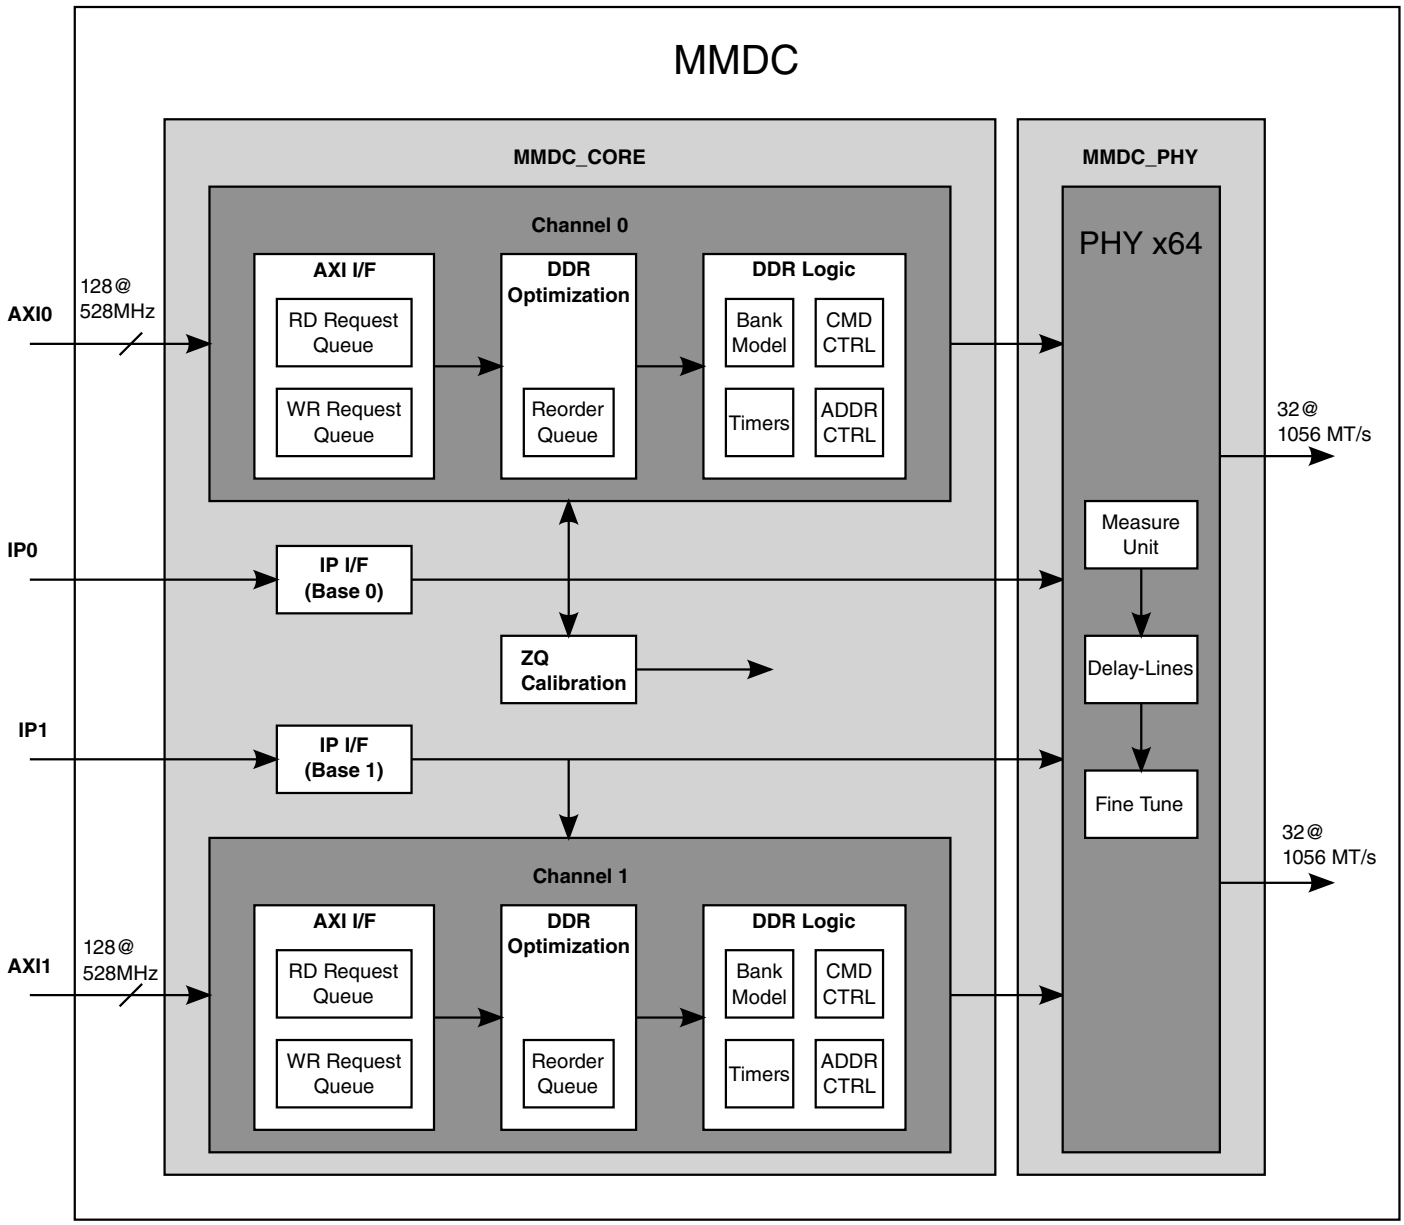

Figure 44-1. MMDC block diagram

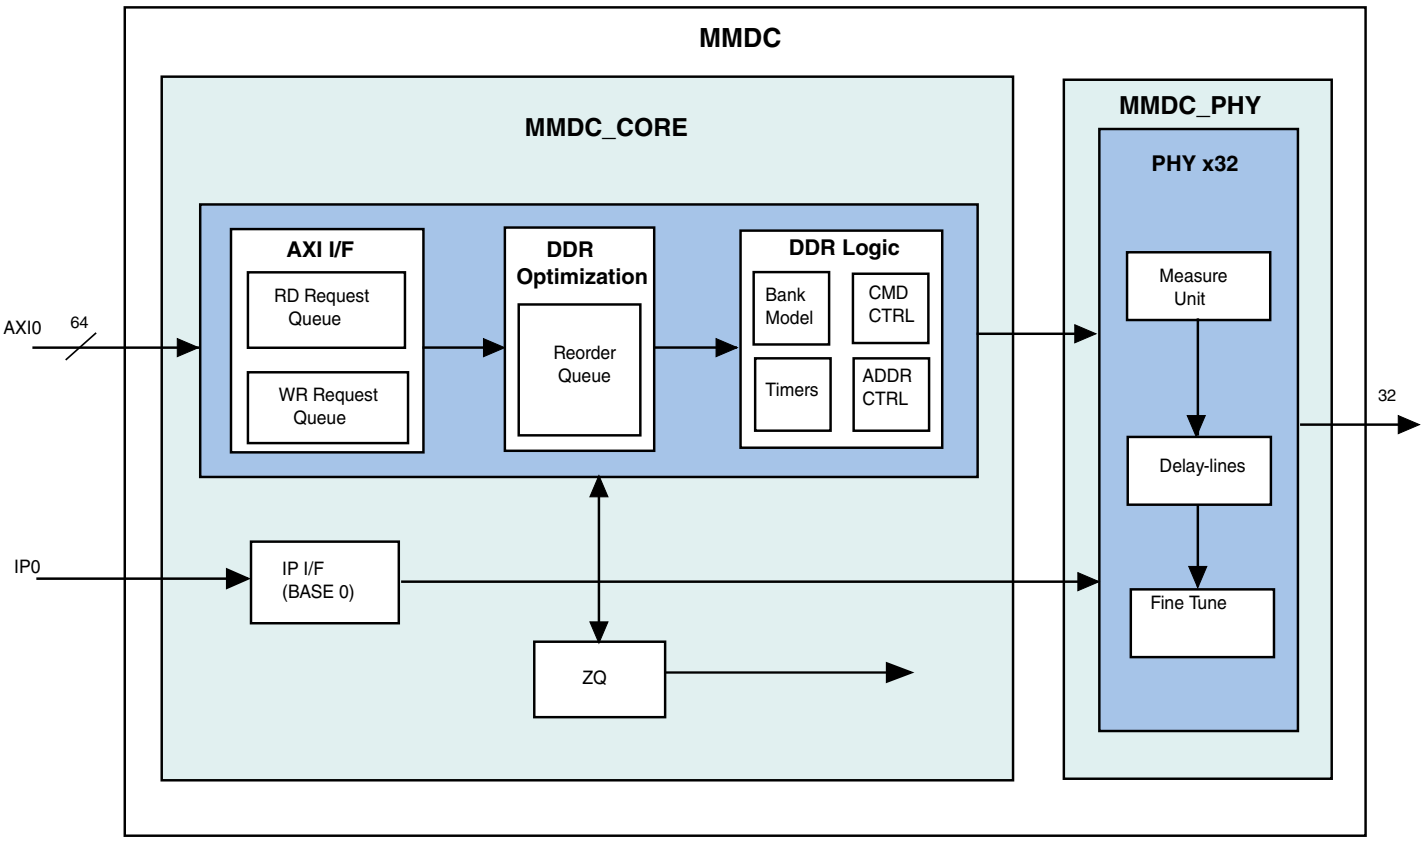

Figure 44-2. MMDC block diagram

MMDC consists of a core (MMDC_CORE) and PHY (MMDC_PHY).

- The core is responsible for communication with the system through an AXI interface, DDR command generation, DDR command optimizations, and a read/write data path.
- The PHY is responsible for the timing adjustment; it uses special calibration mechanisms to ensure data capture margin at a clock rate of up to 528 MHz.

NOTE

The core is composed of two channels, but both channels are only active in LPDDR2 mode. If DDR3 mode is selected, channel1 is not activated and the MMDC communicates with the system through AXI port0.

The internal memory map(configuration registers) of the MMDC can be configured through two IP channels (IP0 and IP1). IP channel 0 is associated with 021B_0000h–021B_08C0h and IP channel1 is associated with 021B_4000h–021B_48C0h.

44.1.1 MMDC feature summary

The table found here summarizes the MMDC features.

Table 44-1. MMDC feature summary

Feature	Details
DDR standards	• LV-DDR3, DDR3 x16, x32, x64 (includes SODIMM) • LPDDR2 2-channels x16, x32 • Does not support LPDDR1MDDR or DDR2

DDR interface	• x16, x32, x64 data bus width
	• Density per DDR device of 256 Mbits–8 Gbits with the following column and row combinations:
	  • Column size of 8–12 bits
	  • Row size of 11–16 bits
	• Two chip selects per channel
	• Up to 4 Gbytes of address space with configurable partitioning between CS0 and CS1 (for LPDDR2 2ch x32 up to 2 Gbytes per channel)
	• Supports burst length of 8 (aligned) for DDR3
	• Supports burst length of 4 for LPDDR2

DDR performance	• MMDC running at up to 528 MHz (1056MT/s), see CCM block for actual clock frequencies supported. • Supports Real-Time priority by means of QoS sideband priority signals from the chip to enable various priority levels in the re-ordering mechanism: real-time, latency sensitive, normal priority. • Page hit/page miss optimizations • Consecutive read/write access optimizations • Supports deep read and write request queues to enable bank prediction. • Drives back the critical word in a read transaction as soon as it is received by the DDR device (does not wait until the whole data phase has been completed). • Keeps tracking of open memory pages • Supports bank interleaving • Special optimization in case of non-aligned wrap accesses in DDR3 mode (burst length 8) **NOTE:** Due to reordering and optimization mechanisms (per different AXI Identifier (ID)), the transactions towards the DDR device may be driven in a different ID order than was received by the AXI master. In a similar fashion, the write response, read response or read data may be driven to the AXI master in a different ID order.

AXI interface	• AXI bus compliant
	• Supports bus transfers of 8, 16, 32 and 128 bits (single accesses and bursts) running at 528 MHz.
	• Supports AXI bursts length of up to 16
	• Supports burst types of WRAP, INCR and FIXED
	• Supports 16 bits AXI ID
	• Write data interleave depth is 1 (no support for Write Data Interleave)
	• Supports write data before address
	• Supports buffered/non-buffered accesses (AWCACHE[0] = 0b means a non-bufferable access and AWCACHE[0] = 1b means a bufferable access). The rest of the CACHE options are not supported
	  • To keep data access coherency between write and read access of the same master, the response signal is sent as follows:
	  • Bufferable write access—BRESP will be sent when last data of the access has entered the MMDC.
	  • Non-bufferable write access—BRESP will be sent when the data was physically written into the external memory device.

Table continues on the next page...

Table 44-1. MMDC feature summary (continued)

Feature	Details

	• Supports four exclusive monitors per configurable ID for only a single access with a size of up to 64 bits
	• Supports AXI responses as follows:
	  • Okay in case the access has been successful or exclusive access failure
	  • Slave error in case of security violation
	  • Exclusive okay in case the read or the write portion of an exclusive access has been successful

DDR calibration and delay-lines.	• Supports various calibration processes which can be performed either automatically (hardware) or manually (software) towards either CS0 or CS1. (At the end of the process the delay-lines will work with one set of results.) The following calibration processes are supported:
	  • ZQ calibration for external DDR device (in DDR3 through ZQ calibration command and in LPDDR2 through MRW command)
	  • Can be handled automatically for ZQ Short (periodically) and ZQ Long (at exit from self-refresh)
	  • Can be handled manually at ZQ INIT
	  • ZQ calibration for i.MX DDR I/O pads for calibrating the DDR driving strength
	  • The sequence can be handled automatically by hardware
	  • The sequence can be handled step by step manually by software
	  • Read data calibration. Adjustment of read DQS with read data byte.
	  • Read DQS gating calibration for DDR3 only. Adjustment of DQS gate with read preamble window.
	  • Write data calibration. Adjustment of write DQS with write data byte.
	  • Write leveling calibration. Adjustment of write DQS with CK (DDR differential clock).
	  • Read fine tuning. Adjustment of up to 7 delay-line units for each read data bit.
	  • Write fine tuning. Adjustment of up to 3 delay-line units for each read data bit.
	  • Periodic delay-line measurement for keeping its accuracy during refresh interval.
	  • Additional fine tuning delay lines to adjust DDR clock delay, DDR clock duty cycle, DQS duty cycle.

Power saving	• Support of dynamic voltage, frequency change and self-refresh mode entry through hardware and software negotiation with the system (request/acknowledge handshake)
	  • Upon hardware or software self-refresh request assertion, further AXI requests are blocked (even before the assertion of the acknowledge).
	  • During self-refresh mode the system may deassert the operating clock of the MMDC for power saving.
	  • During self-refresh mode the clock (CK) that is driven to the DDR device will be gated for power saving.
	• Supports automatic self-refresh and power down entry and exit
	  • In automatic self-refresh, the internal operating clock will be gated for power saving.
	• Supports fast and slow precharge power down in DDR3
	• Automatic active and precharge power down timer per chip select (one chip select can enter power down while the other is still working)
	• While CS (chip-select) is inactive (high) the command and address buses are not toggling for power saving.
	• While DM (data masking) is high the associated DQ bus is not toggling (driven to "0") for power saving.

DDR general	• Configurable timing parameters • Configurable refresh scheme • Page boundary crossing support • Automatically generates precharge command and activates the next row • Supports various ODT control schemes

Table 44-1. MMDC feature summary

Feature	Details
	• Assertion or deassertion of ODT control per read or write accesses and for active or passive CS (chip-select) • Supports MRW and MRR commands for LPDDR2 • Software control in LPDDR2 mode for switching to derated timing parameters and/or update the refresh rate according to temperature sensor • Debug and profiling capabilities

44.2 External Signals

The table found here describes the external signals of MMDC.

Table 44-2. MMDC External Signals

Signal	Description	Pad	Mode	Direction
DRAM_ADDR[15:00]	Address Bus Signals	DRAM_A[15:0]	No Muxing	O
DRAM_CAS	Column Address Strobe Signal	DRAM_CAS	No Muxing	O
DRAM_CS[1:0]	Chip Selects	DRAM_CS[1:0]	No Muxing	O
DRAM_DATA[63:00]	Data Bus Signals	DRAM_D[63:0]	No Muxing	I/O
DRAM_DQM[7:0]	Data Mask Signals	DRAM_DQM[7:0]	No Muxing	O
DRAM_ODT[1:0]	On-Die Termination Signals	DRAM_SDODT[1:0]	No Muxing	O
DRAM_RAS	Row Address Strobe Signal	DRAM_RAS	No Muxing	O
DRAM_RESET	Reset Signal	DRAM_RESET	No Muxing	O
DRAM_SDBA[2:0]	Bank Select Signals	DRAM_SDBA[2:0]	No Muxing	O
DRAM_SDCKE[1:0]	Clock Enable Signals	DRAM_SDCKE[1:0]	No Muxing	O
DRAM_SDCLK[1:0]_N	Negative Clock Signals	DRAM_SDCLK_[1:0]_B	No Muxing	O
DRAM_SDCLK[1:0]_P	Positive Clock Signals	DRAM_SDCLK_[1:0]	No Muxing	O
DRAM_SDQS[7:0]_N	Negative DQS Signals	DRAM_SDQS[7:0]_B	No Muxing	I/O
DRAM_SDQS[7:0]_P	Positive DQS Signals	DRAM_SDQS[7:0]	No Muxing	I/O
DRAM_SDWE	WE signal	DRAM_SDWE	No Muxing	O

44.3 Clocks

The table found here describes the clock sources for MMDC.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 44-3. MMDC Clocks

Clock name	Clock Root	Description
aclk_fast_core_p0	mmdc_ch0_axi_clk_root	Fast clock (channel 1)
aclk_fast_core_p1	GND	Fast clock (channel 2)
ipg_clk_p0	ipg_clk_root	Peripheral clock (channel 1)
ipg_clk_p1	ipg_clk_root	Peripheral clock (channel 2)
aclk_fast_phy_p0	mmdc_ch0_axi_clk_root	Fast clock (channel 1 - PHY)
aclk_fast_phy_p1	GND	Fast clock (channel 2 - PHY)

44.4 Functional Description

This section provides a complete functional description of the block.

44.4.1 Write/Read data flow

44.4.1.1 Write data flow

1. Write requests are received into an 8 entries request FIFO. Access is received only when there are at least two available entries. Each entry holds all of the AXI attributes.
   - If the burst length is greater than 8, the access splits into two accesses: one with burst length 8 and the other with the remainder.
   - The access can be performed as soon as the entire data phase of the associated write request is completed (all data beats were received).
2. A simple round-robin arbitration between the pending read and write accesses is performed, and the pointer to this stage's winner access is sent to the re-ordering buffer.
3. The reordering mechanism is activated to find the winner access, which is the access that best utilizes the DDR bus, based on its dynamic score. For further information see Dynamic scoring mode (Arbitration Winning Conditions).
4. The winner write access at the previous stage is received and is held for dispatch to the DDR logic.
5. When the DDR command control unit is ready to accept the write request, it issues (if needed) a precharge/active command to the DDR device according to the status of the bank model and the parameters of the timers.

6. The DDR logic drives the associated data to the DDR device through the DDR PHY.

44.4.1.2 Read data flow

1. Read requests are received into a 16 entry request FIFO in MMDC if there are at least two available entries. Each entry holds all of the AXI attributes.

NOTE

If the burst length is greater than 8, the access splits into 2 accesses (one with burst length 8 and the other with the remainder).

2. A simple round-robin arbitration between the pending read and write accesses is performed and the pointer to this phase's winner access is sent to the re-ordering buffer.
3. The reordering mechanism is activated to find the winner access, which is the access that best utilizes the DDR bus, based on its dynamic score. For further information see Dynamic scoring mode (Arbitration Winning Conditions).
4. The winner read access at the previous stage is sampled and is held for dispatch to the DDR logic. This read access will be dispatched when there is at least one free slot in the read data buffer to store the data.
5. When the DDR command control unit is ready to accept the read request, it issues (if needed) a precharge/active command to the DDR device according to the status of the bank model and the parameters of the timers.
6. The MMDC PHY samples the read data, and the DDR logic transfers the data to the associated slot in the read data buffer.
7. MMDC transfers the data back to the master.

44.4.2 MMDC initialization

Because the MMDC is disabled when the chip exits reset, no clock is driven to the DDR device and the whole interface towards the DDR device is inactive. The following steps are required to activate the MMDC properly.

NOTE

To guarantee that the DRAM_RESET and DRAM_SDCKE signals are kept low during the power-up and reset sequences of the chip in DDR3 and LPDDR2 modes (as defined by JEDEC), you must connect those signals to pull-down resistors.

1. Set MDSCR[CON_REQ], which sets the configuration request; note that because the MMDC is disabled, there is no need to poll the configuration acknowledge bit at MDSCR[CON_ACK].
2. Configure the desired timing parameters at the MDCFG0, MDCFG1, MDCFG2, and MDOTC registers.
3. Configure the DDR type and other miscellaneous parameters at the MDMISC register.
4. Configure the required delay while leaving reset, at the MDOR register.
5. Configure the DDR physical parameters (density and burst length) at the MDCTL register.
6. Perform a ZQ calibration of the MMDC module to correctly initialize drive strengths.
7. Enable MMDC with the desired chip select at MDCTL[SDE_0] (for chip select 0) and MDCTL[SDE_1] (for chip select 1). At this point, MMDC starts the reset and initialization sequence related to DRAM_RESET/DRAM_SDCKE as defined by JEDEC.
8. Complete the initialization sequence as defined by JEDEC by issuing MRS/MRW commands for (ZQ, ODT, PRE, and so on). To issue those commands, configure the appropriate command and address at the MDSCR register.
9. Program the DDR mode registers by configuring the appropriate command and address at the MDSCR register.
10. Configure the power down and self-refresh entry and exit parameters at the MDPDC and MAPSR registers.
11. Configure the ZQ scheme at the MPZQHWCTRL and MPZQLP2CTRL registers.
12. Configure and activate the periodic refresh scheme at the MDREF register.
13. Deassert the configuration request by clearing MDSCR[CON_REQ].

NOTE

Steps 1 through 5 are non-blocking and can be done in any order.

Upon completion of these steps, MMDC is ready for work and to process AXI accesses.

NOTE

To achieve better timing and better precision, it is recommended that users configure the MMDC PHY delay parameters by operating either the automatic or manual calibration processs. Before starting any calibration process, you must disable the periodic refresh scheme (MDREF[REF_SEL] = 00) and then issue a manual refresh command by configuring MDSCR[CMD] to 2h. For further information, see Calibration Process.

44.4.3 Configuring the MMDC registers

To safely modify MMDC's internal configuration registers, MMDC must be placed into configuration mode.

Use the following steps to enter configuration mode.

1. Issue a configuration request by setting MDSCR[CON_REQ].
2. Poll on configuration acknowledge until it is set at MDSCR[CON_ACK].

At this point, MMDC enters configuration mode and accessing the MMDC registers is permitted.

NOTE

During configuration mode, MMDC prevents further AXI accesses from being acknowledged.

Upon deassertion of MDSCR[CON_REQ], MMDC leaves configuration mode and AXI accesses are processed.

44.4.4 MMDC Address Space

44.4.4.1 Address decoding

MMDC supports up to two consecutive chip selects, each with the same density. In LPDDR2-2ch mode, up to two chip selects per channel are supported.

It is optional to configure the partition between the chip selects through MDASP[CS0_END].

The incoming AXI address bus is 32 bits. MMDC decodes each access as follows:

1. chip select
2. bank number
3. row number
4. column number

The following registers in the MMDC define the DDR address space:

- MDMISC[DDR_4_BANK]—Defines either 4 or 8 banks in the DDR device
- MDCTL[DSIZ]—Defines the DDR data bus width of x16, x32 or x64
- MDMISC[BI]—Defines whether bank interleaving is on or off

- MDCTL[COL]—Defines the column size of the DDR device
- MDCTL[ROW]—Defines the row size of the DDR device

The following tables show address decoding examples for x16 and x32 bit DDR devices when bank interleaving is both on and off. It is assumed that the configration is as follows: 8 banks (3 bits), 15 bit assignment for the row, and 10 bit sassignment for the column. The total density is 256 MWords (512 Mbytes for x16 and 1 Gbyte for x32).

NOTE

Chip selection is done by comparing the 7 most significant address bits (ARADDR[31:25]/AWADDR[31:25]) with MDASP[CS0_END].

NOTE

In cases where this is an access to a non-initialized or disconnected chip select, behavior may be unexpected.

44.4.4.2 Chip select settings

MMDC drives the incoming access to either CS0 or CS1 by comparing the 7 most significant address bits (ARADDR[31:25]/AWADDR[31:25]) with MDASP[CS0_END].

Generally, the total density per chip-select must be the same, and the total density per chip-select must be a power of two.

Creating 4 Gbyte address space with 2 Gbyte CS density and Creating 2 Gbyte address spaces with 1 Gbyte CS density show how to create a continous address space and configure the MMDC accordingly.

44.4.4.2.1 Creating 4 Gbyte address space with 2 Gbyte CS density

If the DDR memory space allocation is 4 Gbytes, only one configuration of chip select partition is allowed.

The register MDASP[CS0_END] should be set to 011_1111 (partition at 2 Gbytes).

The figure below shows the associated memory space. In the case of DDR3 x64, this address space can be acheived by connecting four devices per chip select. Each device is x16 with density of 4 Gbytes.

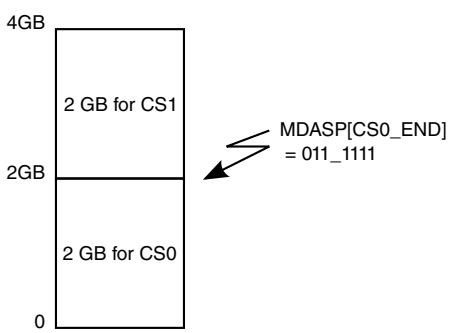

Figure 44-3. Chip select partion—2 Gbytes per chip select

44.4.4.2.2 Creating 2 Gbyte address spaces with 1 Gbyte CS density

If the DDR memory space allocation is 2 Gbytes, there are three options for configuring the chip select partition:MDASP[CS0_END] to 001_1111 (1 Gbyte), MDASP[CS0_END] to 011_1111 (2 Gbytes), and MDASP[CS0_END] to 101_1111 (3 Gbytes).

If DDR memory space allocation is 2 Gbytes, there are three options for configuring the chip select partition:

- MDASP[CS0_END] to 001_1111 (1 Gbyte)
- MDASP[CS0_END] to 011_1111 (2 Gbytes)
- MDASP[CS0_END] to 101_1111 (3 Gbytes)

The figure below shows the associated memory space:

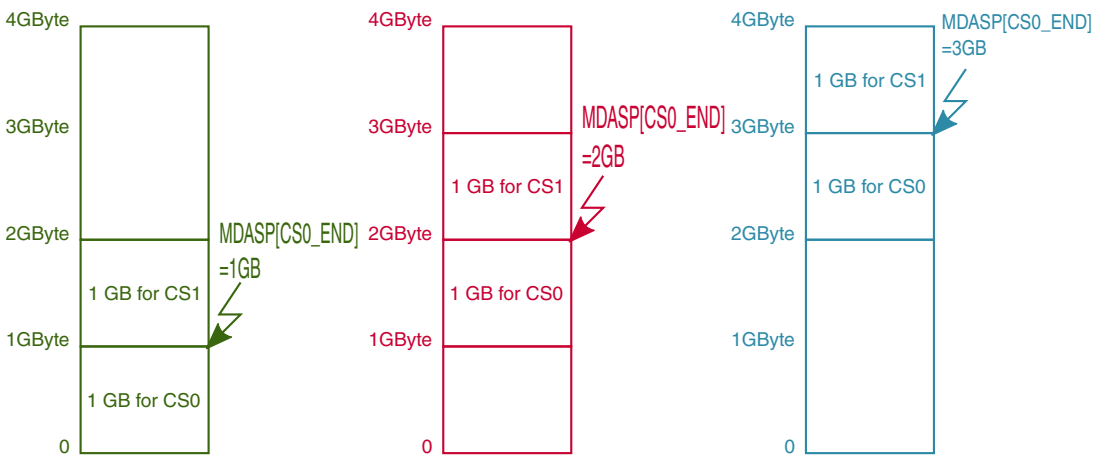

Figure 44-4. Chip select partion—1 Gbyte per chip select

44.4.4.3 Translation of AXI accesses to DDR accessess

44.4.4.3.1 Example 1

Assume the AXI read access has the following attributes:

- Wrap (arburst[1:0] = 10b)
- AXI size of 128 bits (arsize[2:0] = 100b)
- AXI length of 8 (arlen[3:0] = 0111b)
- AXI address with suffix B0h (non-aligned to AXI wrap boundary which is 16Bx8 = 128B = 0x80)

Toward DDR3(MDMISC[DDR_TYPE] = 00b) with the following attributes:

- x32 (MDCTL[DSIZ] = 01b)
- burst length of 8 (MDCTL[BL] = 1b)

In this case, the AXI wrap boundary is every 16Bx8=128B (0x80) and the DDR wrap boundary is every 4Bx8=32B(0x20).

The master expects to fetch the data that is associated with the following addresses: 0xB0, 0xC0, 0xD0, 0xE0, 0xF0, 0x80, 0x90, 0xA0.

The first aligned AXI address that is associated with suffix 0xB0 is with suffix 0x80, and the last wrap AXI address is with suffux 0xFF. Because the AXI master expects to get the first data from AXI address with suffix 0xB0, the MMDC issues the following accesses toward the DDR:

- Read access toward logic address with suffix 0xA0 (DDR boundary is 0x20 and 0xA0 is the closest to 0xB0)

NOTE

Logic address is the address of the column normalized to 1 byte.

- Read access toward logic address with suffix 0xC0
- Read access toward logic address with suffix 0xE0
- Read access toward logic address with suffix 0x80

The MMDC breaks the AXI access into four DDR accesses and returns the read data associated with address 0xB0 to the master first. The read data fetched from address 0xA0 is stored in the internal buffers and is driven back to the master at the end.

44.4.4.3.2 Example 2

Assume the AXI write access has the following attributes:

- Increment (awburst[1:0]=2'b01)
- AXI size of 64bits (awsize[2:0]=3'b011)
- AXI length of 8 (awlen[3:0]=4'b0111)
- AXI address with suffix 0xB0 (aligned as the size of the increment is 8B)

Toward DDR3(MDMISC[DDR_TYPE]=2'b00) with the following attributes:

- x64 (MDCTL[DSIZ]=2'b10)
- burst length of 8 (MDCTL[BL]=1'b1)

In this case, the AXI alignment is every 8B and the DDR boundary is every 8Bx8=64B(0x40).

The master expects to write the data to the following addresses: 0xB0, 0xB8, 0xC0, 0xC8, 0xD0, 0xD8, 0xE0, 0xE8.

The MMDC will issue the following accesses toward the DDR:

- Write access toward logic address with suffix 0x80 (DDR boundary is 0x40 and 0x80 is the closest to 0xB0) while address 0x80 to 0xAF are masked by DM (data masking signal).

NOTE

Logic address is the address of the column normalized to 1 byte.

- Write access toward logic address with suffix 0xC0 while addresses 0xF0 through 0xFF are masked by DM (data masking signal)

The MMDC will break the AXI access into two DDR accesses.

44.4.4.3.3 Example 3

Assume the AXI write access has the following attributes:

- Wrap (awburst[1:0]=2'b10)
- AXI size of 128bits (awsize[2:0]=3'b100)
- AXI length of 4 (awlen[3:0]=4'b0011)
- AXI address with suffix 0x80 (aligned)

Toward DDR3(MDMISC[DDR_TYPE]=2'b00) with the following attributes:

- x64 (MDCTL[DSIZ]=2'b10)
- burst length of 8 (MDCTL[BL]=1'b1)

In this case, the AXI wrap boundary is every 16Bx4=64B (0x40) and the DDR wrap boundary is every 8x8=64B(0x40).

The master expects to write the data to the following addresses: 0x80, 0x90, 0xA0, 0xB0.

Because the AXI wrap boundary and DDR wrap boundary are similar and the starting AXI address is aligned, the MMDC will issue only one access toward the DDR as follows:

- Write access towards logic address with suffix 0x80

NOTE

Logic address is the address of the column normalized to 1 byte.

44.4.4.3.4 Example 4

Assume the AXI write access has the following attributes:

- Increment (awburst[1:0]=2'b01)
- AXI size of 64bits (awsize[2:0]=3'b011)
- AXI length of 2 (awlen[3:0]=4'b0001)
- AXI address with suffix 0x5 (non aligned)

Toward DDR3(MDMISC[DDR_TYPE]=2'b00) with the following attributes:

- x32 (MDCTL[DSIZ]=2'b10)
- burst length of 8 (MDCTL[BL]=1'b1)

In this case the AXI alignment is every 8B (0x8) and the DDR boundary is every 4Bx8=32B(0x20).

The master expects to write the data to the following addresses: 0x5 (with WSTRB=0xE0), 0x8 (till 0xF).

The MMDC will issue one access toward the DDR as follows:

Write access toward logic address with suffix 0x0 (DDR boundary is 0x20 and 0x0 is the closest to 0x0) while address 0x0 till 0x4 are masked by DM (data masking signal) and address 0x10 till 0x1F are also masked by DM.

44.4.4.3.5 Example 5

Assume AXI write access has the following attributes:

- Increment (awburst[1:0]=2'b01)
- AXI size of 64bits (awsize[2:0]=3'b011)
- AXI length of 7 (awlen[3:0]=4'b0001)
- AXI address with suffix 0x10 (aligned)

Toward DDR3 (MDMISC[DDR_TYPE]=2'b00) with the following attributes:

- x64 (MDCTL[DSIZ]=2'b10)
- burst length of 8 (MDCTL[BL]=1'b1)

In this case the AXI alignment is every 8B (0x8) and the DDR boundary is every 8Bx8=64B(0x40).

The master expects to write the data to the following addresses: 0x10, 0x18, 0x20, 0x28, 0x30, 0x38, 0x40, 0x48.

Because the AXI access is not aligned to DDR boundary, which is every 0x40, the MMDC will issue two accesses toward the DDR as follows:

- Write access toward logic address with suffix 0x0 while address 0x0 till 0xF are masked by DM (data masking signal).

NOTE

Logic address is the address of the column normalized to 1 byte.

- Write access towards logic address with suffix 0x40 while addresses 0x50 till 0x7F are masked by DM (data masking signal).

44.4.4.4 Address mirroring

When enabling this feature, address bits DRAM_A3, DRAM_A4, DRAM_A5, DRAM_A6, DRAM_A7, DRAM_A8, DRAM_SDBA0, and DRAM_SDBA1 behave differently according to the associated chip select.

This feature facilitates PCB board routing for devices on chip select 1, which are typically populated on the opposite side of the PCB from the devices on chip select 0.

NOTE

This feature is only supported for DDR3 memories. It is not supported for LPDDR2 memories.

The following table specifies the address mirroring options:

Table 44-6. Address mirroring options

MMDC pin	Chip select 0 pin	Chip select 1 pin
DRAM_A3	DRAM_A3	DRAM_A4
DRAM_A4	DRAM_A4	DRAM_A3
DRAM_A5	DRAM_A5	DRAM_A6
DRAM_A6	DRAM_A6	DRAM_A5
DRAM_A7	DRAM_A7	DRAM_A8
DRAM_A8	DRAM_A8	DRAM_A7
DRAM_SDBA0	DRAM_SDBA0	DRAM_SDBA1
DRAM_SDBA1	DRAM_SDBA1	DRAM_SDBA0

44.4.5 LPDDR2 and DDR3 pin mux mapping

The following table shows the pin mux mapping between LPDDR2 and DDR3. The i.MX DDR I/O pads corresponds with the DDR3 standard.

- In DDR3, all DRAM_DATA, DRAM_SDQS, and DRAM_DQM data lines work with channel 0.
- In LPDDR2, DRAM_DDQS[3:0], DRAM_DATA[31:0] and DRAM_DQM[3:0] work with channel 0. DRAM_SDQS[7:4], DRAM_DATA[63:32], and DRAM_DQM[7:4] work with channel 1.

Table 44-7. LPDDR2 and DRAM pin mux mapping

DRAM I/O pad	LPDDR2 functionality
DRAM_ADDR00	LPDDR2_CA9_P0
DRAM_ADDR01	LPDDR2_CA7_P0
DRAM_ADDR02	LPDDR2_CA8_P0
DRAM_ADDR03	LPDDR2_CA1_P1

44.4.6 Power Saving and Clock Frequency Change modes

44.4.6.1 Power saving general

MMDC supports multiple DDR power saving modes.

NOTE

At default, the power saving modes are disabled. These modes may dramatically decrease the power consumption of DDR memories.

1. Self-refresh entry to the entire DDR device (for both chip select 0 and 1) can be activated through two mechanisms:
   - LPMD (Low Power Mode)
     - Hardware handshaking (LPMD/LPACK) with the clock module in the system
     - Software handshaking by setting the field MAPSR[LPMD] and polling MAPSR[LPACK]
     - Automatic entry by configuring the amount of idle cycle for triggering self-refresh entry through MAPSR[PST] and by clearing MAPSR[PSD]
   - DVFS (Dynamic Voltage and Frequency Change)
     - Hardware handshaking (DVFS/DVACK) with the clock module in the system
     - Software handshaking by setting the field MAPSR[DVFS] and polling MAPSR[DVACK]

NOTE

If hardware or software requests for self-refresh entry were detected by the MMDC (even before the assertion of the LPACK), no write or read accesses will be acknowledged utnil the deassertion of those requests.

2. Automatic active/precharge power down entry to a specific chip select can be activated by configuring the ESDPDC register:
   - PWDT_0/PWDT_1 - define the number of idle cycles before entering power down, can be different value per chip select.
   - SLOW_PD - In case of DDR3 memory is configured to use slow precharge power down then this bit should be set as well.
   - BOTH_CS_PS - The MMDC can either set each chip select independently to power down, according to its idle state, or set both chip selects to power down only if both in idle state for the configured period.
   - Few paramters must be configured in addition:

- Timing parameters at ESDCFG0[tXP and tXPDLL].
- ODT timing at ESDOTC[tAOFPD, tAONPD, tANPD and tAXPD]

NOTE

It is possible to enter certain chip selects to low power consumption while the second chip select is activated.

3. Automatic precharge of all DDR banks to a specific chip select. Can be activated by configuring ESDPDC fields: PRCT_0 and PRCT_1. Each field determines a value loaded to a different chip select.

44.4.6.2 Self refresh and Frequency change entry/exit

As described in Power saving general, the MMDC supports two mechanisms that will cause the DDR device to enter self-refresh mode:

- LPMD (Low Power Mode) - For power saving purposes
- DVFS (Dynamic Voltage and Frequency Change) - For clock frequency changes

While the DDR device is in self-refresh mode, there is no need to provide periodic refresh commands.

The MMDC treates hardware/software handshaking of LPMD/DVFS in the same manner:

- Upon the assertion of LPMD/DVFS request, the following is done:
  - The MMDC blocks any further AXI accesses even before the acknowledge is asserted
  - Completes all opened AXI accesses
  - Closes (precharge) all banks in the appropriate timing
  - Drives self-refresh command by deasserting clock enable signal (DRAM_SDCKE is driven to "0") together with a refresh command. This occurs after satisfying tRP/tRPA from the precharge all command.
  - Deasserts the clock (CK) that is driven to the DDR device
  - Asserts LPMD/DVFS acknowledge (LPACK/DVACK)
  - Allows deassertion of the operating clock of the MMDC (AXI clock)
- Upon the deassertion of LPMD/DVFS request, the following is done:
  - Operating clock of the MMDC must be turned on before LPMD/DVFS is deasserted
  - Starts driving the clock (CK) to the DDR device
  - After satisfying tCKSRX from clock renewal the clock enable signal (DRAM_SDCKE) is asserted
  - LPMD/DVFS acknowledge (LPACK/DVACK) is deasserted

- After satisfying tXS from the assertion of DRAM_SDCKE, a refresh command is driven to the DDR device.
- If ZQ calibration is enabled then tRFC is satisfied from the refresh command and a long ZQ command is driven.
- tZQoper idle cycles are counted after the ZQ command.
- After satisfying tDLLK from the assertion DRAM_SDCKE, the MMDC returns to normal operation.

The figure below shows the timing diagram of the hardware/software handshaking of LPMD/DVFS:

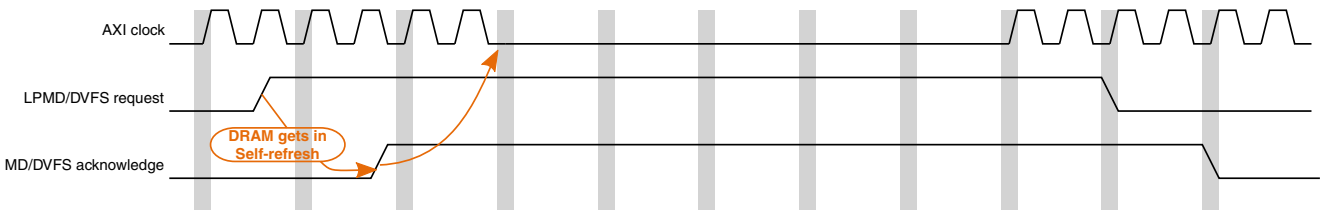

Figure 44-5. LPMD/DVFS Hardware/Software Handshaking

Note for self-refresh:

- As soon as LPMD or DVFS requests are detected by either hardware or software handshaking, the MMDC will deassert the AXI ARREADY/AWREADY signals immediately to block further requests from the system.
- In case of automatic self-refresh, the internal operating clock will be negated to save power.

44.4.7 Reset

44.4.7.1 Hard reset

When hard reset is asserted (aresetn is driven to "0") while warm reset is deasserted (warm_reset is driven to "0"), the entire MMDC will be initialized, including configuration/status registers and state machines.

In order to access the DDR device, the MMDC will then have to be reconfigured.

44.4.7.2 Warm reset

The MMDC supports warm reset signal. The warm reset signal must envelop the hard reset signal and then the MMDC will reset all the internal registers. The only registers that are not reset are those that are essential for returning it to normal operation without repeating the initialization sequence and without losing data stored in the memory (configuration/status registers won't be initialized).

For the successful operation of warm reset, the following steps must be performed:

- The MMDC must enter self-refresh mode. This can be achieved by either LPMD or DFVS requests
- Wait for LPMD or DVFS acknowledge
- Assert warm reset signal (i.e. drive warm_reset to "1")
- Assert hard reset signal (i.e. drive aresetn to "0")
- Deassert hard reset signal
- Deassert warm reset
- Get out of the LPMD/DVFS mode

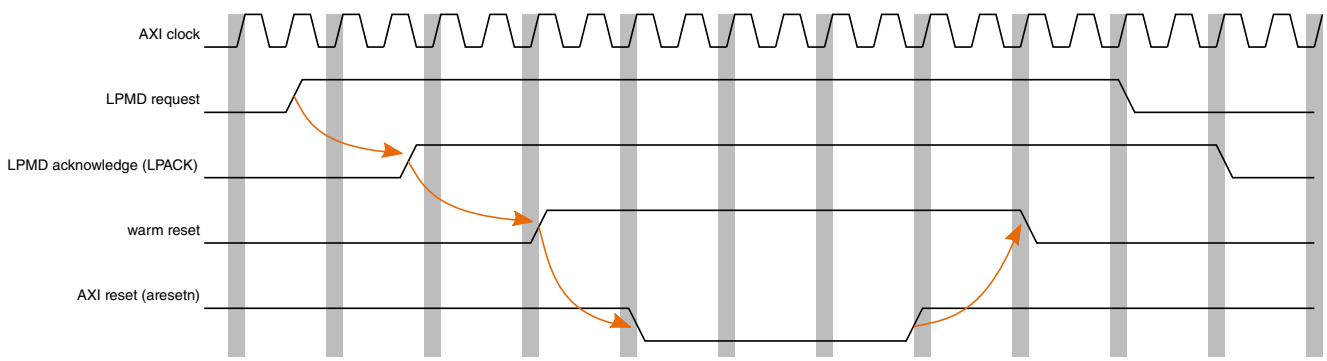

Figure 44-6. Warm Reset Diagram

44.4.7.3 Software reset

The MMDC supports software reset. When software reset is configured then the MMDC will reset all the internal registers except those that are essential for returning to normal operation without repeating the initialization sequence or without losing data stored in the memory (configuration/status registers won't be initialized).

The following steps should be performed for successful operation of software reset:

- The MMDC should enter self-refresh mode. This can be achieved by either LPMD or DFVS request.
- Wait for LPMD or DVFS acknowledge

- Assert software reset, by setting MDMISC[RST]
- Get out of the LPMD/DVFS mode

Normal operation can be resumed.

44.4.8 Refresh Scheme

The MMDC supports various automatic refresh options which can be configured via the MDREF register.

The periodic auto refresh can be triggered by the following clocks:

- 32KHz clock
- 64KHz clock
- MMDC operating clock

The refresh scheme of the MMDC is flexible and allows the system to configure the desired AXI accesses delay/latency in each refresh cycle.

The table below shows an example of four configurations of the refresh cycles that will be handled by the MMDC. Each configuration meets a refresh rate of 3.9us (tREFI, refresh command every 3.9us).

Table 44-8. MMDC Refresh Scheme

Option number	Description	REFR	REF_SEL	REF_CNT	DDR hang time
1	Issue 8 refresh commands every 31,250 ns	0x7 (8 refreshes)	0x2 (64KHz)	not needed	tRFC * 8
2	Issue 4 refresh commands every 15,625ns	0x3 (4 refreshes)	0x1(32KHz)	not needed	tRFC * 4
3	Issue 2 refresh commands every 7800ns	0x1(2 refreshes)	0x3 (fast counter)	7800/2.5 = 3120 (0xC30)	tRFC * 2
4	Issue 1 refresh command every 3900 ns	0x0 (1 refresh)	0x3 (fast counter)	3900/2.5 = 1560(0x618)	tRFC

44.4.9 Burst Length options towards DDR

The MMDC supports two kinds of burst lengths which can be configured through MDCTL[BL] as follows:

- In DDR3 mode, only burst length 8 can be used.
- In LPDDR2 mode, only burst length 4 can be used.

In DDR3 mode read/write accesses to the DDR are always 8 words (x16, x32, x64) and aligned in according to JEDEC standards.

In case of AXI INCREMENT, accesses that are not aligned the irrelevant data is masked in write acesses and ignored in read accesses. In case of AXI WRAP accesses, even if the access is not aligned, then the MMDC provides an internal optimization mechanism for better efficiency of the DDR data bus.

44.4.10 Exclusive accesses handling

The MMDC contains four exclusive monitors, each for dedicated ID as configured in MAEXIDR0 and MAEXIDR1.

- If legal read exclusive is received by the MMDC, the associated monitor is turned on.
- While the monitor is turned on upon legal write exclusive, the monitor will be turned off and the write will be completed successfully with EXOKAY.
- The following rules must be met for successful exclusive access:
  - Aligned access (the AXI address is aligned to the AXI size)
  - AXI single access (AXI burst length isn't greater than 1)
  - AXI size of up to 64 bits
  - AXI non-cachable access (i.e. ARCACHE[1]/AWCACHE[1] is equal "0" or ARCACHE[1]/AWCACHE[1] is equal "1" while ARCACHE[3:2]/ AWCACHE[3:2] are equal "00")
  - AXI ID that matches one of the four exclusive IDs

Exclusive read behavior (first bullet also correct for non-exclusive accesses):

- In case of security violation, the read is blocked and is not sent to DDR. There are two options for response:
  - If ARCR_SEC_ERR_EN (MAARCR[30]) is high, SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- If AXI exclusive rules violation occurs (as described above), the read access is not blocked and is sent to DDR. The data will be fetched and be driven to the master, but the type of response may be unpredicted.
- If none of the above occurs, the read is sent to the DDR. The exclusive monitor will be turned on and the response is ExOKAY
- If additional legal AXI read exclusive is received with the same ID before the AXI exclusive write, the monitor will be updated with the latest attributes.

Exclusive write behavior (first bullet also correct for non-exclusive accesses):

- In case of security violation, the write is blocked and is not sent to DDR, but the monitor will be kept on. There are two options for response:
  - If ARCR_SEC_ERR_EN (MAARCR[30]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- In case of AXI exclusive rules violation (as described above), the write is blocked and is not sent to DDR. In that case the type of response may be unpredicted.
- In case the exclusive write access has different AXI attributes, but the same ID as the read exclusive access, the write is blocked and is not sent to DDR and the monitor will be turned off. There are two options for response:
  - If ARCR_EXC_ERR_EN (MAARCR[28]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- In case of regular (non exclusive) write access is received to the same address or overlapping addresses then the write will be sent to the DDR and the monitor will be turned off.
- In case of legal write exclusive access is received with the same attributes as the read exclusive access while the monitor is on (no write accesses occured to the same address between the read exclusive and write exclusive), then the write is sent to DDR and the response is EXOKAY. But, if the legal write exclusive is received while the monitor is off, the write is blocked and there are two options for response.
  - If ARCR_EXC_ERR_EN (MAARCR[28]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.

44.4.11 AXI Error Handling

The MMDC supports the AXI responses listed here.

- In case of AXI exclusive violation there are two options for response:
  - If MAARCR[28] is high then SLVError is issued towards the Master, Otherwise OKAY response is sent to the Master

NOTE

In case of read error MMDC drives zeros on the read data bus

44.5 Performance

44.5.1 Arbitration and reordering mechanism

44.5.1.1 Arbitration General

The following specifies arbitration and reordering flow in MMDC towards the DDR.

- AXI read and write accesses are sampled in the associated queue.
- Read/write arbitration is handled to select the winning access.
- Winning access is sampled in the reordering queue
- Reordering mechanism is handled between valid requests that reside in the reordering queue to select the access that will be dispatched to the DDR.
  - The reordering is held in order to optimize the accesses and to maximize the utilization of the DDR bus
  - As soon as the reordered access is completed (indicated by end of response or data phase) then it is erased from the associated queue and the MMDC is ready to receive the next available access from the master

In general, the reordering/arbitration mechanism is based on dynamic priority mechanism, which compares dynamic priorities between valid entries in the reordering queue and issues the entry with highest dynamic priority towards the DDR Logic.

The selection of the winning access is based on two modes, which can be activated together, as following:

- Real time channel mode:
  - Accesses with QoS='f' (i.e. awqos[3:0]/arqos[3:0] = "f") will bypass all other requests towards the DDR
- Dynamic scoring mode:
  - The arbitration mechanism is based on dynamic priority. Relevant for the accesses with QoS smaller than 'f' or when real time channel mode is disabled.

NOTE

Due to re-ordering and optimization mechanism (per different AXI ID), the transactions towards the DDR may be driven in a different ID order they were received by the AXI master. In similar way, the write response, read response or read data may be driven to the AXI master in a different ID order.

44.5.1.2 Real time channel mode

When real time mode is enabled (i.e MAARCR[ARCR_RCH_EN] = "1") , all requests with QoS='f' (i.e. awqos[3:0]/aqqos[3:0] = "f") will bypass all other pending accesses towards the DDR. This mode is enabled by default.

44.5.1.3 Dynamic scoring mode (Arbitration Winning Conditions)

The arbitration between pending accesses in the MMDC is handled according to a dynamic priority of each access.

The dynamic priority (may be also called score) is calculated according to a sum of some factors (final_score[3:0]), where part of them may be updated dynamically. The following will specify each scoring factor:

- MAARCR[ARCR_PAG_HIT] (Page hit score) - A static score which is taken into account in case the pending access has a page hit
- MAARCR[ARCR_ACC_HIT] (Access hit score) - A static score, which is taken into account in case the current access type (read/write) is the same as the access that has been dispatched to the DDR previously
- MAARCR[ARCR_DYN_JMP] (Dynamic jump score) - A dynamic score which is given to any pending access in case it was not chosen in the arbitration. The dynamic jump counter is limited by maximum value which is set in MAARCR[ARCR_DYN_MAX] .
- QoS score which is indicated through a sideband 4bits AXI signals (awqos[3:0]/ aqqos[3:0]) and is driven by the AXI master per access

Note: In order to prevent an overflow in the total sum of scores, a clipping is held and selects the maximum score value of 'f' once a total scores sum is greater than 'f'.

The figure below shows the dynamic score calculations

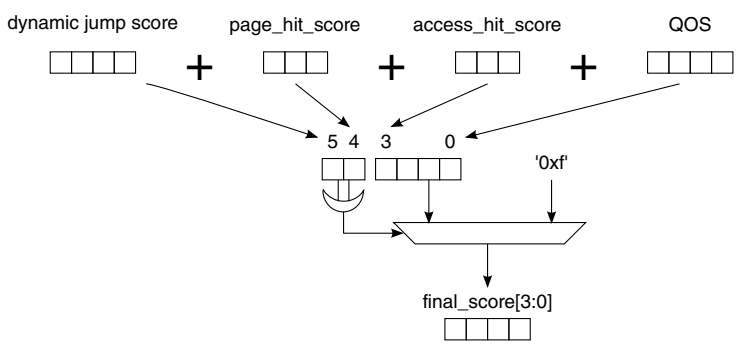

Figure 44-7. Dynamic score/priority calculation

44.5.1.4 Guarding (aging) mechanism

The guarding mechanism (may be also called aging) is used to prevent a starvation of accesses.

As soon as the dynamic jump score reaches its maximum value (MAARCR[ARCR_DYN_MAX]) then each time a pending request was not chosen in the arbitration, the "guarding" counter is incremented by 1. When the "guarding" counter reaches its predefined value, set in MAARCR[ARCR_GUARD], the associated request gets the highest priority and will be chosen in the next arbitration cycle towards the DDR unless a real time channel (i.e access with QoS ="f") is arrived.

Note: In case real time channel has arrived then the dynamic score of the non real time channels won't increment in order to prevent a case where the "guarding" counter of more than one access has reached its limit.

44.5.2 Prediction mechanism

When prediction mechanism is enabled (i.e by configuring MDMISC[MIF3_MODE]) then the MMDC predicts the chip-select, bank address and row address that is going to be issued towards the DDR before the access is physically dispatched towards DDR device.

That mechanism enables to prepare the DDR device with future accesses and improves the overall DDR performance.

This prediction mechanism operates in parallel to the reordering mechanism and may yield a prediction based on 3 levels of pending accesses:

1. Access in first stage of pipeline.
2. Valid access on AXI bus either read channel or write channel.
3. Valid access on special bus from arbitration - this access is chosen by the arbitration as the next miss access in its buffers

44.5.3 Special Optimization for accesses towards DDR3

In case an AXI read/write wrap non-aligned access is acknowledged in DDR3 mode with the same wrap boundary as the DDR wrap boundary then the MMDC will make an optimization and issue only one access towards the DDR, although all the accesses towards the DDR3 must be aligned.

For example: AXI write access with size of 128bits (awsize[2:0]=3'b100), length of 4 (awlen[3:0]=4'b0011) towards DDR3 x64 (burst length 8). In that case the AXI wrap boundary is 16Bx4=64B (0x40) and the DDR3 wrap boundary is 8Bx8=64B (0x40). If, for example, the AXI access is towards AXI address with suffix of 0x10 (non-aligned to 64B boundary) then the MMDC will get from the AXI master the data that is associated with addresses 0x10, 0x20, 0x30, 0x0. The MMDC will rearrange internally the data so it

will match DDR3 alignment as following: 0x0, 0x10, 0x20, 0x30 and drive it in one access towards the DDR to address 0x0. The alternative was to issue two accesses towards the DDR with address 0x0 with different data masking

NOTE

In read wrap access the same optimization is handled, while as soon as the critical AXI word is fetched from the DDR then it is driven immediately to the AXI master without buffering. Based on the example above, the master expects to fetch first the data that is associated with address 0x10. Therefore the MMDC will issue read access from address 0x0 of the DDR and as soon as the data that is associated with address 0x10 is received then it will be driven back immediately to the master even before fetching the data of the furhter addresses.

44.6 MMDC Debug

44.6.1 Hardware debug monitor

The MMDC has a hardware debugging mechanism that monitors each access that is driven to the MMDC from channel 0.

Every time this mechanism is enabled (setting of MADPCR0[DBG_EN] to "1") then each access that will be dispatched to the DDR will be also observed in the I/O pads (i.e. over ipp_do_ddr_debug[50:0]). The content of this bus is described in the table below.

Table 44-9. Hardware monitor debugging

Signal Name	Number of Bits	Description
acc_addr	[31:0]	AXI ADDRESS of the selected access
acc_type	1	access type of the selected access. "0 indicates write. "1" indicates read.
acc_id	[15:0]	AXI transaction ID of the selected access
valid_strobe	1	indication for a valid request . This signal will be asserted for 1 clock cycle

The fields above are organized as following:

MMDC_DEBUG[50:0] = {1'b0,valid_strobe,acc_id,access_type,addr}

These signals are sent to IOMUX, in IOMUX user can configure it to be output from the chip for debug usage.

44.6.2 Step By Step (SBS) software monitor

The MMDC has a Step By Step (SBS) software debugging mechanism that monitors each access that is driven to the MMDC.

Every time this mechanism is trigerred then one AXI access will be dispatched to the DDR and in parallel its attributes will be observed in a status register.

Once the "step by step" is enabled (i.e. MADPCR0[SBS_EN] is "1") then all accesses to the DDR device will be halted.

Setting MADPCR0[SBS] to "1" will dispatch the access that is pending in the head of the MMDC queue (read or write). Upon every setting of MADPCR0[SBS]:

- The AXI attributes of the access will be sampled in the associated MASBS0 and MASBS1 fields
- MADPCR0[SBS] will be cleared automatically.

Setting again MADPCR0[SBS] to "1" will dispatch the next pending access in the MMDC queue.

44.7 MMDC Profiling

The profiling mechanism provides the ability to calculate the DDR utilization together with read and write accesses statistics towards DDR per given period of time.

MMDC supports the following profiling counters:

- MADPSR0 (Total cycles count) - Indicates the total amount of cycles of the profiling period (up to 2^32 cycles)
- MADPSR1 (Busy cycles count) - Indicates the total busy cycles during the profiling period. Busy cycles are any MMDC clock cycles where the internal state machine is not idle. If any read or write requests are pending in the FIFOs, the MMDC is not idle.
- MADPSR2 (Total read accesses count) - Indicates the total read accesses towards MMDC during the profiling period
- MADPSR3 (Total write accesses count) - Indicates the total write accesses towards MMDC during the profiling period
- MADPSR4 (Total read bytes count) - Indicates total bytes that were read from MMDC during the profiling period
- MADPSR5 (Total write bytes count) - Indicates total bytes that were written to MMDC during the profiling period

All profiling items described above are disabled by default. The following describes how to control the profiling mechanism:

- MADPCR0[DBG_EN] enables profiling.
- MADPCR0[PRF_FRZ] stops/freezes the profiling for example in case user wishes to perform DDR profiling per specific task. In order to resume profiling then MADPCR0[PRF_FRZ] should be cleared.
- MADPCR0[DBG_RST] clears all profiling counters
- MADPCR0[CYC_OVF] indicates whether an overflow occured in the total cycles counter (i.e. total amount of cycles are greater than 2^32) . This field can only cleared by writing '0'.

Read/Write statistics can be collected per specific AXI ID (16bits). The following fields in MADPCR1 register determines which AXI-ID or AXI-ID's to monitor:

- PRF_AXI_ID defines which AXI IDs are taken for profiling. Default values is 16'h0.
- PRF_AXI_ID_MASK defines which bits from PRF_AXI_ID will be compared with AXI ID of read/write access. "1" means to monitor the associated bit and "0" means don't care. Default value is 16'h0000, meaning all IDs are not monitored

So the AXI-IDs to be monitored are calculated according to the following equation:

(AXI-ID & PRF_AXI_ID_MASK) Xnor (PRF_AXI_ID & PRF_AXI_ID_MASK)

For example if AXI ID's between A100 till A1FF are wished to be monitored then the following should be configured:

- PRF_AXI_ID = A100
- PRF_AXI_ID_MASK = FF00

Table 44-10. i.MX 6Dual/6Quad AXI ID

44.8 LPDDR2 Refresh Rate Update and Timing Derating

LPDDR2 devices may have a temperature sensor that is used to determine an appropriate refresh rate and whether AC timing derating is required. The status of the temprature sensor can be read through MRR command from LPDDR2 MR4 register.

The MMDC supports refresh update and timing derating mechanism on the fly. The following specify how to use that mechanism:

- Perform periodic polling on MR4 LPDDR2 register using MRR command
- Read MDMRR register and analyze the MR4 indication
- In case refresh rate update and/or AC timing derating is required then it is needed to update MDREF and/or MDMR4[tRCD_DE, tRC_DE, tRAS_DE, tRP_DE, tRRD_DE] parameters

NOTE

MDMR4[tRCD_DE, tRC_DE, tRAS_DE, tRP_DE, tRRD_DE] are referred to the associated values configured at MDCFG3LP[tRC_LP, tRP_LP, tRCD_LP], MDCFG1[tRAS], MDCFG2[tRRD]

- Assert MDMR4[UPDATE_DE_REQ]
- When the MMDC switch to the new values then an acknowledge will be indicated at MDMR4[UPDATE_DE_ACK]

44.9 DLL Off mode

DLL Off mode is supported only in DDR3 and allows operation of the DDR in low frequency (i.e. below 125MHz as defined in JEDEC standard).

For further details refer to DLL-off Mode chapter in the standard.

The following steps should be executed in order to switch from DLL on to DLL off mode:

- Assert CON_REQ signal and wait to CON_ACK assertion.
- Disable power down timers that can conflict with this sequence, such as: MAPSR[PSD], MDPDC[PWDT_1], MDPDC[PWDT_0], MDPDC[PRCT_0], MDPDC[PRCT_1].
- Execute precharge all banks command (via MDSCR).
- Execute MRW command to MR1 and disable RTT Nom (A9,A6,A2 =0) and DLL ON (A0 =1).
- Execute MRW command to MR2 in order to update CWL to 6.
- Execute MRW command to MR0 in order to update CL to 6.
- De-assert CON_REQ signal.
- Enter self refresh mode. For further information refer to Self refresh and Frequency change entry/exit.
- At self refresh entry acknowledge , change to the desired frequency.
- Exit self refresh mode.
- Assert CON_REQ and wait to CON_ACK assertion.
- Enable Pull Down resistors on DQS (through the I/O-MUX).
- Configure the MMDC register as following:
- Update tCWL =6 and tCL =6 to meet the values configured in the DDR device. (MDCGFG0, MDCFG1)
- Disable ODT resistor (i.e. set MPODTCTRL to "0").
- Disable DQS gating (i.e. set MPDGCTRL0[DG_DIS] to "1").
- Enable required power down timers that were disabled, such as: MAPSR[PSD], MDPDC[PWDT_1], MDPDC[PWDT_0], MDPDC[PRCT_0], MDPDC[PRCT_1].
- De-assert CON_REQ and wait for de-assertion of CON_ACK.

The following steps should be executed in order to switch from DLL off to DLL on:

- Execute precharge all banks command (via MDSCR).

- Enter self refresh mode. For further information refer to Self refresh and Frequency change entry/exit.
- At self refresh entry acknowledge, change to the desired frequency.
- Exit self refresh mode
- Assert CON_REQ and wait to CON_ACK assertion.
- Disable power down timers that can conflict with this sequence, such as: MAPSR[PSD], MDPDC[PWDT_1], MDPDC[PWDT_0], MDPDC[PRCT_0], MDPDC[PRCT_1].
- Execute MRW command to MR1 and enable RTT Nom (A9,A6,A2) and DLL ON (A0 =0).
- Execute MRW command to MR0 to reset the DLL (A8) and update CL value
- Execute MRW command to MR2 in order to update CWL value.
- Execute ZQ commnad.
- Reconfigure MMDC BLOCK
- Update tCWL and tCL to meet the values configured to the memory. (MDCGFG0, MDCFG1)
- Enable ODT resistor (i.e. MPODTCTRL register)
- Enable DQS gating (i.e. set MPDGCTRL0[DG_DIS] to "0").
- Disable Pull Down resistors on DQS (through the I/O-MUX).
- Enable required power down timers that were disabled, such as: MAPSR[PSD], MDPDC[PWDT_1], MDPDC[PWDT_0], MDPDC[PRCT_0], MDPDC[PRCT_1].
- De-assert CON_REQ and wait for de-assertion of CON_ACK.

44.10 ODT Configuration

The MMDC supports two DRAM_ODT signals (DRAM_ODT for each DRAM_CS) in DDR3 mode in order to allow the DDR device to turn on/off its termination resistors. The MMDC suggests various configuration for the assertion of the ODT signals as well as configuration of several related timing.

The following specifies the options for configuring the assertion of DRAM_ODT signals:

- Assert DRAM_ODT signal for the non active DRAM_CS in write. For example : when this bit asserted - if writing to DRAM_CS0 the DRAM_ODT of DRAM_CS1 will be asserted. This is done by setting MPODTCTRL[0] to "1"
- Assert DRAM_ODT signal for the active DRAM_CS in write by by setting MPODTCTRL[1] to "1"
- Assert DRAM_ODT signal for the non active DRAM_CS in read by by setting MPODTCTRL[2] to "1"
- Assert DRAM_ODT signal for the active DRAM_CS in read by by setting MPODTCTRL[3] to "1"

MDOTC register controls the timing for the DRAM_ODT signals assertion.

NOTE

tODTLon determines the delay between DRAM_ODT signal and the associated RTT, where according to JEDEC standard it equals WL(write latency) - 2. Therefore, the value configured to MDOTC[tODTLon] field should correspond with the value configured to MDCGFG1[tCWL].

In precharge power down mode , when all banks are closed, the assertion of ODT corresponds with tAOFPD and tAONPD which are configured in MDOTC register.

The figure below shows timing diagram of DRAM_ODT and RTT signals while MPODTCTRL[0] is set to "1" (i.e. assertion of DRAM_ODT to the non active DRAM_CS in write access command) and MDOTC[tODTLon] is set to 4.

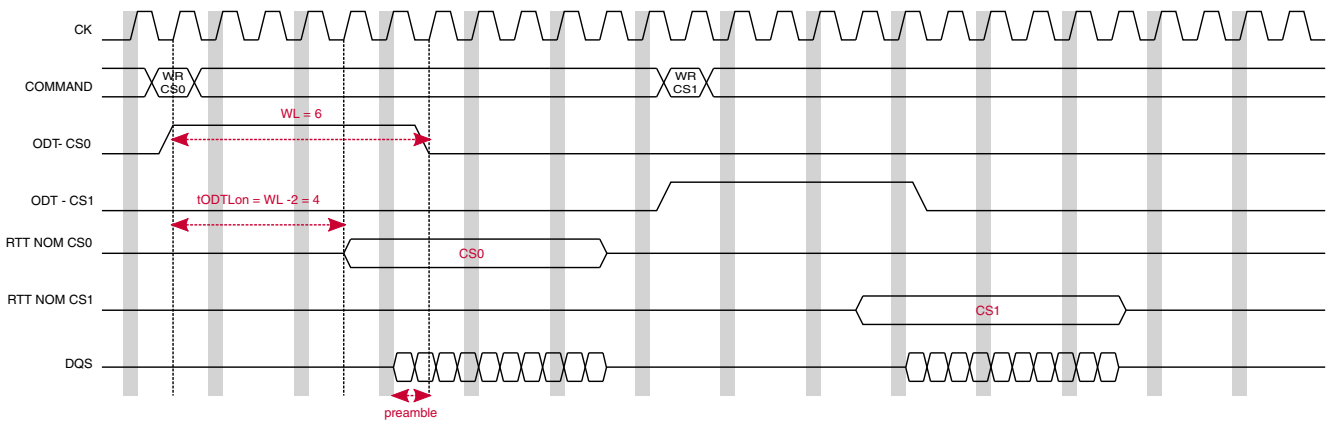

Figure 44-8. ODT - Timing Diagram DDR3 WL=6, BL=8

44.11 Calibration Process

The MMDC offers various calibration processes that are used to obtain better timing accuracy, board skew compensation and I/O pad driving strength adjustment.

Each calibration process can be performed either automatically (hardware) or manually (software), though the manual method is typically reserved for debugging purposes. The following calibration processes are supported:

NOTE

Power saving features should be disabled before the calibration process begin. (Such as: MDPDC[PWDT#], MDPDC[PRCT#], MAPSR[PSD])

- ZQ calibration for external DDR device (in DDR3 through ZQ calibration command and in LPDDR2 through MRW command)
  - Can be handled automatically for ZQ Short (periodically) and ZQ Long (at exit from self-refresh)
  - Can be handled manually at ZQ INIT
- ZQ calibration for i.MX DDR I/O pads for calibrating the DDR driving strength
  - The sequence can be handled automatically by hardware
  - The sequence can be handled step by step manually by software
- Read DQS gating calibration for DDR3 only. Adjustment of DQS gate with read preamble window. For further information refer to Read DQS Gating Calibration
- Read data calibration. Adjustment of read DQS with read data byte. For further information refer to Read Calibration
- Write data calibration. Adjustment of write DQS with write data byte. For further information refer to Write Calibration
- Write leveling calibration. Adjustment of write DQS with CK (DDR differential clock). For further information refer to Write leveling Calibration
- Read fine tuning. Adjustment of up to 7 delay-line units for each read data bit.
- Write fine tuning. Adjustment of up to 3 delay-line units for each read data bit.

NOTE

Before starting any calibration process that involves the DDR3 device MPR mode or write leveling calibration, the following should be done:

- Disable the periodic refresh scheme (i.e. setting MDREF[REF_SEL] = "00") and then issue manual refresh command burst by configuring MDSCR[CMD]= 0x2. At the end of the calibration it is needed to enable the periodic refresh scheme.
- Disable the automatic power saving mode (i.e set MAPSR[PSD] = "1").

44.11.1 Delay-line

Each of the calibration processes controls several delay-lines for aligning data and strobes.

By default the delay-line is configured to generate 1/4 clock cycle of delay. The maximum delay that may be issued by the delay-line, while configured to the value 127, is as following:

- Under best-case conditions, -40C, 1.21V - 1.6ns.
- Under worst-case conditions, 125C, 0.99V - 3.8ns

Moreover, when the operating clock is at the maximum allowed frequency, as appeared in the features list, then the delay-line is capable to issue a configurable delay of up to 1/2 clock cycle.

NOTE

At the beginning of the calibration process the initial value of the delay-line must be a valid value (i.e. the strobes must be somewhere among the associated data window) though it might not be the optimal value. The delay-line calibration should be done after Read DQS gating and write-leveling calibrations.

In order to generate an adequate delay during normal operation of the MMDC the delay-line is going through an automatic measurement process during the refresh period of the DDR device

44.11.2 ZQ calibration

The MMDC supports ZQ calibration process to calibrate the driving strength of the i.MX DDR I/O pads as well as driving ZQ commands to calibrate the external DDR device driving strength.

The first i.MX ZQ calibration (after booting the processor) is performed prior to turning on the MMDC. Subsequent i.MX ZQ calibrations may be executed in parallel to the DDR ZQ calibration. The MMDC supports 2 types of ZQ calibration commands: short and long.

The ZQ long calibration is executed during power up sequence, when existing self-refresh mode or when exiting slow precharge power down (DLL lock can be done in parallel). The ZQ short calibration is executed periodically according to a configurable timer defined by MPZQHWCTRL[ZQ_HW_PER].

The field MPZQHWCTRL[ZQ_MODE] determines whether the MMDC will execute ZQ calibration to i.MX DDR I/O pads and/or issue ZQ short/long command to the DDR device.

The MMDC supports both automatic (hardware) and manual (software) ZQ calibration process for the i.MX DDR I/O pads.

It is possible to perform automatic (hardware) ZQ calibration only once (i.e. non-periodical) by asserting MPZQHWCTRL[ZQ_HW_FOR].

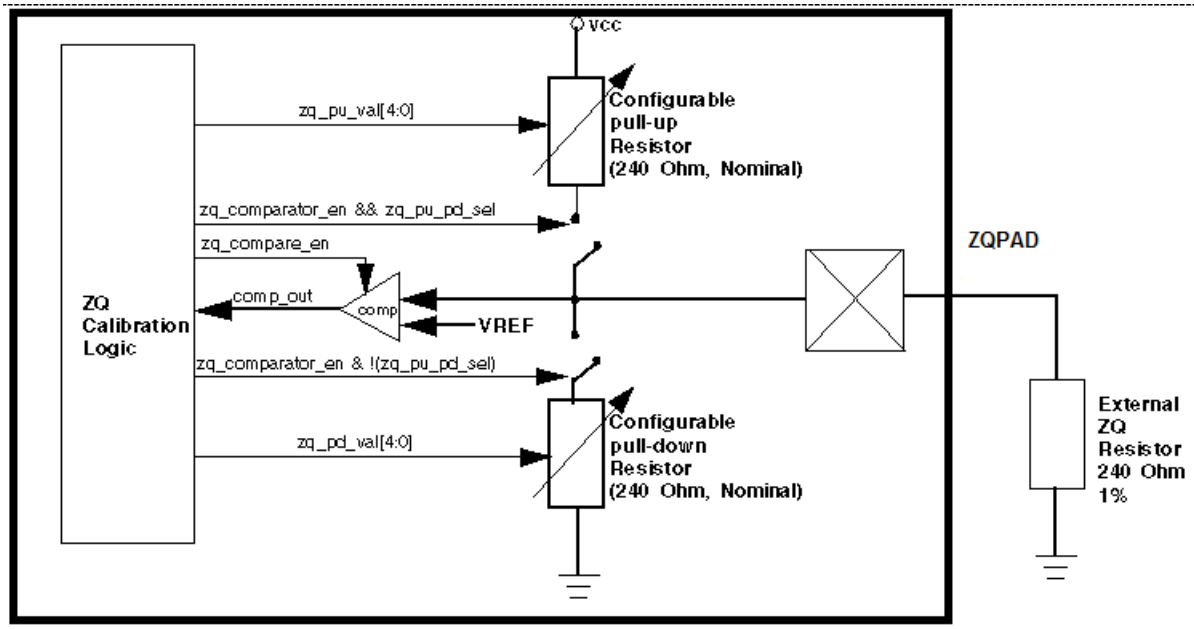

Figure 44-9. MMDC ZQ IF with PAD

44.11.2.1 ZQ automatic (hardware) calibration process

The ZQ automatic calibration lasts 11 steps. 5 steps for the pull up resistors calibration and 6 for the pull down resistors calibration.

The calibration control interface with ZQ pin is described below:

The calibration process is as follows:

44.11.2.1.1 ZQ automatic Pull-up calibration

The MMDC automatically performs a handshaking mechanism with the i.MX ZQ calibration pad as follows:

1. The MMDC drives zq_comparator_en to "1"
2. The MMDC waits few cycles according to MPZQHWCTRL[EARLY_COMPARATOR_EN_TIMER]
3. The MMDC drives zq_pu_pd_sel to "1" for indication of pull-up calibration and drives zq_pu_val[4:0] = 5'b00000
4. MMDC drives zq_pu_val[4] to "1"
5. MMDC asserts zq_compare_en
6. MMDC waits few cycles according to MPZQSWCTRL[ZQ_CMP_OUT_SMP] before sampling the comparator output (i.e zq_comp_out). If zq_comp_out is "1" then it means that the output voltage is greater than Vdd/2 (i.e. internal resistor is less than 240 ohm) and drives bit zq_pu_val[4] to "1" else it drives zq_pu_val[4] to "0"

7. MMDC deasserts zq_compare_en
8. MMDC repeats steps 4- 7for zq_pu_val bits 3 to 0
9. MMDC drives ZQ calibration result to MPZQHWCTRL[ZQ_HW_PU_RES]
10. MMDC advances to pull-down calibration

44.11.2.1.2 ZQ automatic Pull-down calibration

1. The MMDC drives zq_pu_pd_sel to "0" for indication of pull-down calibration and drives zq_pd_val[4:0] = 5'b00000
2. MMDC drives zq_pd_val[4] to "1"
3. MMDC asserts zq_compare_en
4. MMDC waits few cycles according to MPZQSWCTRL[ZQ_CMP_OUT_SMP] before sampling the comparator output (i.e zq_comp_out). If zq_comp_out is "1" then it means that the output voltage is greater than Vdd/2 (i.e. internal resistor is less than 240 ohm) and drives bit zq_pd_val[4] to "0" else it drives zq_pd_val[4] to "1"
5. MMDC deasserts zq_compare_en
6. MMDC repeats steps 12- 15 for zq_pd_val bits 3 to 0
7. MMDC drives ZQ calibration result to MPZQHWCTRL[ZQ_HW_PD_RES]
8. MMDC deassert zq_comparator_en to indicate the completion of the ZQ calibration

44.11.2.2 ZQ software calibration process

The ZQ calibration can be done also in software. However since software ZQ calibration is much slower than hardware calibration it should be used mainly for debugging.

Software should configure the ZQ calibration parameters (Pull-up or Pull-down and their value) then assert the MPZQSWCTRL[ZQ_SW_FOR] bit. Then software should wait till ZQ_SW_FOR is de-asserted and use ZQ_SW_RES status bit in order to calculate the next ZQ calibration parameters.

44.11.2.3 ZQ calibration commands

Before the MMDC can issue a ZQCL/ZQCS command to the memory it should precharge all memory banks and wait tRP period. A single ZQ command can be issued to all devices as long as the devices don't share the same ZQ resistor.

When the MMDC issues the ZQ command it should also drive A10 (long or short command) and CS (0, 1 or both).

The MMDC must keep the memory lines quiet (except for CK) for the ZQ calibration time as defined in the Jedec (512 cycles for ZQCL after reset, 256 for other ZQCL and 64 for ZQCS).

44.11.3 Read DQS Gating Calibration

The read DQS gating calibration is used to adjust the read DQS gating with the middle of the read DQS preamble.

The DQS gating includes a delay of up to 7 cycles (The delay is chosen according to two fields MPDGCTRL#[DG_HC_DEL#] and MPDGCTRL#[DG_DL_ABS_OFFSET#]

Each DQS has its own delay-line. The DQS gating process can be done for all DQS in parallel.

NOTE

In LPDDR2 mode hardware Read DQS gating should be disabled and Pull-up/pull-down resistors on DQS/DQS# should be enabled while ODT resistors must be disconnected.

In DDR3_x64 mode activation of the calibration is done by setting MPDGCTRL0[HW_DG_EN] at address 0xBASE0_083C

44.11.3.1 Hardware DQS Gating Calibration

- There are two modes of operations:
  - Calibration with the MPR (Multi Purpose Register)
  - Calibration with MMDC pre-defined values

44.11.3.1.1 Hardware DQS Calibration with MPR

The following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as requried by the standard.
2. Enter the DDR device into MPR mode through MRS commands
3. Configure the MMDC to work with MPR mode by asserting MPPDCMPR2[MPR_CMP]
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window
5. Start the calibration process by asserting MPDGCTRL0[HW_DG_EN]

44.11.3.1.2 Hardware DQS Calibration with pre-defined value

In case pre-defined mode is used, (i.e. MPPDCMPR2[MPR_CMP]) is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access to the external DDR device by setting MPSWDAR0[SW_DUMMY_WR] = 1 (MMDC will generate internally write access without intervention of the system towards bank 0, row 0, column 0)
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window
5. Start the calibration process by asserting MPDGCTRL0[HW_DG_EN]

   The following steps will be executed automatically by the MMDC for both modes (MPR and Pre-defined value):

6. MMDC waits till the read DQS delay-line is updated with the absolute delay value for all bytes at MPDGCTRL#[DG_HC_DEL#] and MPDGCTRL#[DG_DL_ABS_OFFSET#] and also satisfying the Tmod + 4 requirement
7. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC] assuming that the data has arrived from the DDR device.
8. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point. If the comparison passes then MMDC advances to step 14
9. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
10. MMDC increments the read DQS gating delay of each byte by half cycle (i.e. MPDGCTRL#[DG_HC_DEL#] + 1)
11. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC] assuming that the data has arrived from the DDR device.
12. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8).
13. If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 9-12. If the comparison passes then MMDC stores the value of the temporary low boundary and advances to next step

14. MMDC increments the read DQS gating delay-line of each byte by half cycle (i.e. MPDGCTRL#[DG_HC_DEL#] + 1) and issue measurement process of the read DQS gating delay-line to update itself with the new value
15. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC] assuming that the data has arrived from the DDR device.
16. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
17. If the comparison passes then it indicates that the read DQS gating is asserted inside the read preamble window and it is needed to repeat steps 14-16. If the comparison fails then MMDC stores the value of the temporary upper boundary and starts searching the adequate low and high boundaries
18. MMDC returns to the temporary low boundary minus half cycle and issue measurement process of the read DQS gating delay-line to update itself with the new value
19. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC] assuming that the data has arrived from the DDR device.
20. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
21. If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 22-23. If the comparison passes then MMDC stores the value of the adequate low boundary and advances to step 24
22. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
23. MMDC increments the read DQS gating delay of each byte by 1 (i.e. MPDGCTRL#[DG_DL_ABS_OFFSET#] + 1) and issue measurement process of the read DQS gating delay-line to update itself with the new value and advances to step 19
24. MMDC returns to the temporary upper boundary minus half cycle and issue measurement process of the read DQS gating delay-line to update itself with the new value
25. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC] assuming that the data has arrived from the DDR device.
26. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
27. If the comparison passes then it indicates that the read DQS gating is asserted inside the read preamble window and it is needed to repeat steps 28-29. If the comparison fails then MMDC stores the value minus 1 of the adequate upper boundary and advances to step 30

28. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
29. MMDC increments the read DQS gating delay of each byte by 1 (i.e. MPDGCTRL#[DG_DL_ABS_OFFSET#] + 1) and issue measurement process of the read DQS gating delay-line to update itself with the new value and advances to step 25
30. After the MMDC finds the window boundary (lower and upper) of each read data byte then it stores the average between lower and upper boundaries at the associated MPDGCTRL#[DG_DL_ABS_OFFSET#] and issue measurement process of the read DQS delay-line to update itself with the new value.
31. MMDC indicates that the read DQS gating calibration had finished by setting MPDGCTRL0[HW_DG_EN] = 0
32. Exit the DDR device from MPR mode through MRS command
33. Read the upper boundary that was found: MPDGHWST#[HW_DG_UP#]. This field is 11 bits, 7 LSB bits correspond to MPDGCTRL#[DG_DL_ABS_OFFSET#] upper limit value and 4 MSB bits correspond to MPDGCTRL#[DG_HC_DEL#] upper limit value.
34. Set MPDGHWST#[HW_DG_UP#][6:0] to MPDGCTRL#[DG_DL_ABS_OFFSET#].
35. Set (MPDGHWST#[HW_DG_UP#][10:7] - 1) to MPDGCTRL#[DG_HC_DEL#]. (We set the DQS gating value to be the upper limit value minus 1 half cycle)

44.11.3.2 SW read DQS gating Calibration

- There are two modes of operations:
- Calibration with the MPR (Multi Purpose Register)
- Calibration with MMDC pre-defined values

44.11.3.2.1 SW read Calibration with MPR

The following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Enter the DDR device into MPR mode through MRS commands
3. Configure the MMDC to work with MPR mode by asserting MPPDCMPR2[MPR_CMP]
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window

44.11.3.2.2 SW read Calibration with pre-defined value

In case pre-defined mode is used, (i.e. MPPDCMPR2[MPR_CMP]) is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calicration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access (with any legal DDR address) to external DDR device
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window

   The following steps should be executed automatically by the MMDC for both modes (MPR and Pre-defined value):

5. Configure the read DQS delay-line to issue zero delay by setting MPDGCTRL#[DG_DL_ABS_OFFSET#] = 0 and MPDGCTRL#[DG_HC_DEL#] = 0
6. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
7. Wait 16 DDR cycles till the read DQS delay-line is updated with the absolute delay value for all bytes
8. Issue read command (with the legal DDR address chosen in step 3) from the external DDR device
9. Waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC]) assuming that the data has arrived from the DDR device.
10. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point. If the comparison passes then advance to step 15
11. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
12. Increment the read DQS gating delay of each byte by half cycle (i.e. MPDGCTRL#[DG_HC_DEL#] + 1)
13. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC]) assuming that the data has arrived from the DDR device.
14. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 11 - 14. If the comparison passes then advance to step 15

15. Store the temporary lower boundary and start searching the temporary upper boundary
16. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
17. Increment the read DQS gating delay of each byte by half cycle (i.e. MPDGCTRL#[DG_HC_DEL#] + 1)
18. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC] assuming that the data has arrived from the DDR device.
19. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8).
20. If the comparison passes then it indicates that the read DQS gating is asserted inside the read preamble window and it is needed to repeat steps 16-19. If the comparison fails then it is needed to store the value of the temporary upper boundary and starts searching the adequate low and high boundaries
21. Load the temporary low boundary minus half cycle into the associated MPDGCTRL#[DG_HC_DEL#]
22. Reset the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
23. Increment the read DQS gating delay of each byte by 1 (i.e. MPDGCTRL#[DG_DL_ABS_OFFSET#] + 1) and force the delay line to measure itself and to issue the requested read DQS delay by configuring MPMUR[FRC_MSR] = 1
24. Issue read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC]) assuming that the data has arrived from the DDR device.
25. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
26. If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 22-26. If the comparisons passes then advance to the next step.
27. Store the adequate lower boundary
28. Load the temporary upper boundary minus half cycle into the associated MPDGCTRL#[DG_HC_DEL#]
29. Reset the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
30. Increment the read DQS gating delay of each byte by 1 (i.e. MPDGCTRL#[DG_DL_ABS_OFFSET#] + 1) and force the delay line to measure itself and to issue the requested read DQS delay by configuring MPMUR[FRC_MSR] = 1

31. Issue read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG_CMP_CYC] assuming that the data has arrived from the DDR device.
32. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
33. If the comparison passes then it is needed to repeat steps 29-32. If the comparisons fails then advance to the next step.
34. Reset the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
35. Store the adequate upper boundary.
36. Keep the MPDGCTRL#[DG_DL_ABS_OFFSET#] value of the upper limit.
37. Set MPDGCTRL#[DG_HC_DEL#] = (MPDGCTRL#[DG_HC_DEL#] - 1). (We set the DQS gating value to be the upper limit value minus 1 half cycle)
38. Issue the requested read DQS delay by configuring MPMUR[FRC_MSR] = 1
39. Exit the DDR device from MPR mode through MRS command

44.11.4 Read Calibration

The read calibration is used to adjust the read DQS with read data byte.

It is assumed that the read DQS gating calibration process is completed prior to the read calibration.

NOTE

In DDR3 mode, the activation of the calibration is done by setting MPRDDLHWCTL[HW_RD_DL_EN] at address 0xBASE0_0860. In LP2_x16, LP2_x32 the activation of the calibration of each channel is done by setting MPRDDLHWCTL[HW_RD_DL_EN] at address 0xBASE0_0860 and MPRDDLHWCTL[HW_RD_DL_EN] at address 0xBASE1_0860 respectively.

44.11.4.1 Hardware (automatic) Read Calibration

- There are two modes of operations:
- Calibration with the MPR (Multi Purpose Register)/DQ calibration(LPDDR2)
- Calibration with MMDC pre-defined values

44.11.4.1.1 Hardware (automatic) Calibration with MPR (DDR3) /DQ Calibration (LPDDR2)

The following steps should be executed:

1. Precharge all active banks (can be done through MDSCR) as requried by the standard.
2. Enter the DDR device into MPR/DQ calibration mode through MRS/MRW commands.
3. Configure the MMDC to work with MPR/DQ calibration mode by asserting MPPDCMPR2[MPR_CMP].
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window.
5. Start the calibration process by asserting MPRDDLHWCTL[HW_RD_DL_EN].

44.11.4.1.2 Hardware (automatic) Calibration with pre-defined value

In case pre-defined mode is used, i.e. MPPDCMPR2[MPR_CMP] is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access to the external DDR device by setting MPSWDAR0[SW_DUMMY_WR] = 1 (MMDC will generate internally write access without intervention of the system towards bank 0, row 0, column 0)
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window
5. Start the calibration process by asserting MPRDDLHWCTL[HW_RD_DL_EN]

   The following steps will be executed automatically by the MMDC for both modes (MPR and Pre-defined value):

6. MMDC waits till the read delay-line is updated with the absolute delay value for all bytes at MPRDDLCTL[RD_DL_ABS_OFFSET#] and also satisfying the Tmod + 4 requirement
7. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device.
8. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails

then it indicates that the initial read DQS isn't inside the read DQ window and the MMDC generates an error for the associated byte at MPRDDLHWCTL[HW_RD_DL_ERR#] . If the comparison passes then MMDC advances to next step.

9. MMDC resets the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
10. MMDC decrements the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) and issue measurement process of the read delay-line to update itself with the new value.
11. MMDC drives read command to the DDR external devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device
12. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the low read boundary of the associated byte for each byte at MPRDDLHWST0/1[HW_RD_DL_LOW#] . If the comparison passes then MMDC repeats steps 9-11. If all read data comparisons fail then the MMDC advances to the next step
13. The MMDC start seeking the upper boundary and sets the read delay line absolute offset of each byte to the initial value + 1 as determined at step 4 and issue measurement process of the read delay-line to update itself with the new value
14. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
15. MMDC drives read command to the DDR external devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device
16. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the upper read boundary of the associated byte for each byte at MPRDDLHWST0/1[HW_RD_DL_UP#] . If the comparison passes then MMDC increments the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) and issue measurement process of the read delay-line to update itself with the new value.
17. If all read data comparisons fail then the MMDC advances to the next step. otherwise, MMDC repeats steps 14-16.
18. After the MMDC finds the window boundary (lower and upper) of each read data byte then it stores the average between lower and upper boundaries at the associated MPRDDLCTL[RD_DL_ABS_OFFSET#] and issue measurement process of the read delay-line to update itself with the new value.
19. MMDC indicates that the read data calibration had finished by setting MPRDDLHWCTL[HW_RD_DL_EN] = 0

20. Exit the DDR device from MPR/DQ calibration mode through MRS/MRW commands

44.11.4.2 SW Read Calibration

- There are two modes of operations:
- Calibration with the MPR (Multi Purpose Register)/DQ calibration(LPDDR2)
- Calibration with MMDC pre-defined values

44.11.4.2.1 Calibration with MPR(DDR3)/DQ calibration(LPDDR2)

The following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Enter the DDR device into MPR/DQ calibration mode through MRS/MRW commands
3. Configure the MMDC to work with MPR/DQ calibration mode by asserting MPPDCMPR2[MPR_CMP]
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window

44.11.4.2.2 Calibration with pre-defined value

In case pre-defined mode is used, i.e. MPPDCMPR2[MPR_CMP] is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as requried by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access (with any legal DDR address) to external DDR device.
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window

   The following steps will be executed manually by SW for both modes (MPR/DQ calibration and Pre-defined value):

5. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1

6. Wait 16 DDR cycles till the read delay-line is updated with the absolute delay value for all bytes
7. Issue read command (with any legal DDR address) from the external DDR device
8. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial read DQS isn't inside the read DQ window. If the comparison passes then advance to next step.
9. Reset the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
10. Decrement the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#])
11. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
12. Issue read command (with the legal DDR address chosen in step 7) from the external DDR device and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device
13. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the low read boundary of the associated byte at of each byte . If the comparison passes then repeat steps 9-12. If all read data comparisons fail then advance to the next step.
14. Start seeking the upper boundary and set the read delay line absolute offset of each byte to the initial value + 1 as determined at step 4
15. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
16. Resets the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
17. Issue read command (with the legal DDR address chosen in step 7) from the external DDR device
18. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the upper read boundary of the associated byte at of each byte. If the comparison passes then increment the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSET#])
19. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
20. If all read data comparisons fail then advance to the next step, else repeat steps 16-19
21. After finding the window boundary (lower and upper) of each read data byte then calculate the average between lower and upper boundaries and store the associated average at MPRDDLCTL[RD_DL_ABS_OFFSET#]

22. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
23. Exit the DDR device from MPR/DQ calibration mode through MRS/MRW commands.

44.11.5 Write Calibration

The write calibration is used to adjust the write DQS with write data byte. It is assumed that the read calibration process is completed prior to the write calibration.

NOTE

In DDR3_x64 and LP2_1ch_x64 modes, the activation of the calibration is done by setting MPWRDLHWCTL0[HW_WR_DL_EN] at address 0xBASE0_0864

In LP2_2ch_x16, LP2_2ch_x32 the activation of the calibration of each channel is done by setting MPWRDLHWCTL0[HW_WR_DL_EN] at address 0xBASE0_0864 and MPWRDLHWCTL0[HW_WR_DL_EN] at address 0xBASE1_0864 respectively

44.11.5.1 HW (automatic) Write Calibration

The following steps should be executed:

1. Make sure that the initial value that is configured in the write delay line absolute offset of each byte (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#]) will place the write DQS somewhere inside the write DQ window
2. Configure the pre-defined value, which reflects the value that will be written and compared through the write calibration, to MPPDCMPR1[PDV1, PDV2]
3. Assert MPWRDLHWCTL0[HW_WR_DL_EN]

   The following steps will be executed automatically:

4. MMDC waits till the write delay-line is updated with the absolute delay value for all bytes at MPWRDCTL[WR_DL_ABS_OFFSET#]
5. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to MPWRDLHWCTL[HW_WR_DL_CMP_CYC]) assuming that the data has arrived to the DDR device.
6. MMDC drives read command to the same address from the external DDR

7. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial write DQS isn't inside the write DQ window and the MMDC generates an error for the associated byte at MPWRDLHWCTL[HW_WR_DL_ERR#] . If the comparison passes then MMDC advances to next step.
8. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
9. MMDC decrements the write delay line absolute offset of each byte by 1 (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#]) and issue measurement process of the write delay-line to update itself with the new value.
10. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to MPWRDLHWCTL[HW_WR_DL_CMP_CYC]) assuming that the data has arrived to the DDR device
11. MMDC drives read command to the same address from the external DDR
12. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the low write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_LOW#] . If the comparison passes then MMDC repeats steps 8-11. If all data comparisons fail then the MMDC advances to the next step
13. The MMDC start seeking the upper boundary and sets the write delay line absolute offset of each byte to the initial value + 1 as determined at step 4 and issue measurement process of the write delay-line to update itself with the new value
14. MMDC resets the rd fifo (to the inverted pre-defined value) and its pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
15. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to MPWRDLHWCTL[HW_WR_DL_CMP_CYC]) assuming that the data has arrived to the DDR device.
16. MMDC drives read command to the same address from the external DDR
17. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the upper write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_UP#] . If the comparison passes then MMDC increments the write delay line absolute offset of each byte by 1 (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#]) and issue measurement process of the write delay-line to update itself with the new value.
18. MMDC repeats steps 14-17. If all data comparisons fail then the MMDC advances to the next step
19. .After the MMDC finds the window boundary (lower and upper) of each write data byte then it stores the average between lower and upper boundaries at the associated

MPWRDLCTL[WR_DL_ABS_OFFSET#] and issue measurement process of the write delay-line to update itself with the new value.

20. MMDC indicates that the write data calibration had finished by setting MPWRDLHWCTL[HW_WR_DL_EN] = 0

44.11.5.2 SW Write Calibration

The following steps should be executed:

NOTE

It is recommended to perform the write calibration using the HW method. The SW method is provided for debug purposes only.

1. Make sure that the initial value that is configured in the write delay line absolute offset of each byte (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#]) will place the write DQS somewhere inside the write DQ window
2. Configure the pre-defined value, which reflects the value that will be written and compared through the write calibration, to MPPDCMPR1[PDV1, PDV2]
3. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR[FRC_MSR] = 1
4. Wait 16 DDR cycles till the write delay-line is updated with the absolute delay value for all bytes
5. Issue write command to any legal DDR address of the external DDR device
6. Issue read command, to the address written previously, from the external DDR device
7. Compare the read data byte to the associated byte in the pre-defined value for all bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial write DQS isn't inside the write DQ window. If the comparison passes then advance to next step.
8. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
9. Decrement the write delay line absolute offset of each byte by 1 (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#])
10. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR[FRC_MSR] = 1
11. Issue write command to any legal DDR address of the external DDR device
12. Issue read command, to the address written previously, from the external DDR device
13. Compare the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed

to store the low write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_LOW#] . If the comparison passes then repeat steps 8-12. If all data comparisons fail then advance to the next step.

14. Start seeking the upper boundary and set the write delay line absolute offset of each byte to the initial value + 1
15. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR[FRC_MSR] = 1
16. Reset the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
17. Issue write command to any legal DDR address of the external DDR device
18. Issue read command, to the address written previously, from the external DDR device
19. Compare the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the upper write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_UP#]. If the comparison passes then increment the write delay line absolute offset of each byte by 1.
20. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR[FRC_MSR] = 1
21. If all read data comparisons fail then advance to the next step else repeat steps 16-20.
22. .After finding the window boundary (lower and upper) of each write data byte then calculate the average between lower and upper boundaries and store the associated average at MPWRDLCTL[WR_DL_ABS_OFFSET#]
23. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR[FRC_MSR] = 1

44.11.6 Write leveling Calibration

The write leveling calibration can generate a delay between the clock and the associate DQS of up to 3 cycles as following: (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle).

Write leveling calibration can be executed automatically(HW) or manually (SW).

The automatic calibration process can only detect the optimal DQS to clock delay to within 1 cycle. In extreme cases in which the DDR3 memory is placed far from the microcontroller (long address/command/clock trace lengths), the skew between the DQS and clock may exceed 1 cycle. If this is the case, it is the user's responsibility to both understand that their design causes the DQS to clock skew to exceed 1 cycle and to indicate this manually in the MPWLDECTRL0/1[WL_CYC_DEL#]. It is highly recommended to keep the DDR3 memory as close to the microcontroller as possible,

especially in embedded system designs. When using fly-by topology, the user should calculate the PCB flight time of the clock signal to the furthest placed DDR3 memory to ensure less than 1 cycle skew between DQS and clock.

NOTE

In LPDDR2 mode Write-leveling calibration should be disabled.

In DDR3_x64 mode activation of the calibration is done by setting MPWLGCR[HW_WL_EN] at address 0xBASE1_0808

NOTE

It is essential to route the first bit in each data byte group (D0, D8, D16, D24, D32, D40, D48, D56) from the DDR3 memory to the same data bus bits on the controller. The DDR3 memory outputs the state of the DRAM clock during the write leveling calibration. If any of these are not routed properly, the controller will have no information regarding the state of the DRAM clock during calibration. In previous designs in which write leveling calibration was not performed, the board designer would often swap data bits within each byte group to make the data bus routing cleaner and less susceptible to noise and impedance mismatch. This can still be done with DDR3 so long as the requirement of properly routing D0, D8, D16, D24, D32, D40, D48, D56 is maintained.

44.11.6.1 Hardware Write Leveling Calibration

The following steps should be executed:

1. Configure the external DDR device to enter write leveling mode through MRS command
2. Activate the DQS output enable by setting MDSCR[WL_EN]
3. Active automatic calibration by setting MPWLGCR[HW_WL_EN]

   The following steps will be executed automatically by the MMDC:

4. MMDC enters write leveling mode, counts 25 + 15 cycles and drives the DQS pads as output while the DQ pads will remain inputs. In parallel the MMDC configures the write leveling delay line to "0" (i.e. MPWLDECTRL0[WL_DL_ABS_OFFSET#] = 0) and issue measurement process of the writ-leveling delay-line to update itself with the new value
5. MMDC drives one DQS pulse to the DDR external device

6. MMDC waits 16 cycles (to guarantee that the DQ prime data is stable) and samples the associated prime DQ bit (for example for DQS1 the MMDC samples DQ[8])
7. MMDC increments the write leveling delay line by 1/8 cycle and perform measurement process in order to load the updated value to the associated delay-line
8. MMDC repeates steps 5-7 till the write leveling delay is 1 cycle
9. MMDC checks the 8 bit prime DQ results for each DQS and finds the first transition from 0 to 1. If no transition is found then the MMDC indicates an error at MPWLGCR[HW_WL_ERR#]
10. MMDC stores the value that issues the last "0" on the prime DQ before the transition and loads it to the write leveling delay-line. The MMDC initiates a fine-tune process by incrementing the delay-line values by 1 step (which is 1/256 part of a cycle) till detecting the most accurate transition from 0 to 1
11. Upon completion of this process the MMDC de-asserts the MPWLGCR[HW_WL_EN] and update the most accurate value of the delay-line at the associated MPWLDECTRL#[WL_DL_ABS_OFFSET#]
12. MMDC perform measurement process in order to load the most accurate value to the associated delay-line
13. User should issue MRS command to exit write leveling mode
14. The user should read the results of the associated delay-line at MPWLDECTRL#[WL_DL_ABS_OFFSET#] and in case the user estimates that the reasonable delay may be above 1 cycle then the user should indicate it at MPWLDECTRL#[WL_CYC_DEL#]. Moreover the user should indicate it in MDMISC[WALAT] field. For example, if the result of the write leveling calibration is 100/256 parts of a cycle, but the user estimates that the delay is above 2 cycles then MPWLDECTRL#[WL_CYC_DEL#] should be configured to 2, so the total delay will be 2 and 100/256 parts of a cycle
15. Return the DQS output enable to functional mode by deasserting MDSCR[WL_EN]

44.11.6.2 SW Write Leveling Calibration

The following steps should be executed:

NOTE

It is recommended to perform the write calibration using the HW method. The SW method is provided for debug purposes only.

1. Configure the external DDR device to enter write leveling mode through MRS command
2. Activate the DQS output enable by setting MDSCR[WL_EN]

3. Set the write-leveling delay-line offset to "0" by configuring MPWLDECTRL0[WL_DL_ABS_OFFSET#] = 0
4. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC_MSR] = 1
5. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW_WL_EN] = 1 together with MPWLGCR[SW_WL_CNT_EN] = 1
6. Issue an IP read command from MPWLGCR. If MPWLGCR[SW_WL_EN] = 0 then the SW write-leveling result is valid at MPWLGCR[WL_SW_RES#].
7. Increment the write leveling delay line by 1/8 cycle (i.e add 0x20 to {MPWLDECTRL0[WL_HC_DEL#],MPWLDECTRL0[WL_DL_ABS_OFFSET#]})
8. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC_MSR] = 1
9. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW_WL_EN] = 1
10. Repeate steps 6-9 till the edge of CK was detected (i.e the write-leveling result switched from "0" to "1")
11. Store the value that issues the last "0" on the prime DQ before the transition and load it to the write leveling delay-line and start fine tuning process to detect the exact switch from "0" to "1"
12. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC_MSR] = 1
13. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW_WL_EN] = 1
14. Issue a IP read command from MPWLGCR. If MPWLGCR[SW_WL_EN] = 0 then the SW write-leveling result is valid at MPWLGCR[WL_SW_RES#].
15. Increment the write leveling delay line by 1 step (i.e add 0x01 to MPWLDECTRL0[WL_DL_ABS_OFFSET#])
16. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC_MSR] = 1
17. Issue an IP read command from MPWLGCR. If MPWLGCR[SW_WL_EN] = 0 then the SW write-leveling result is valid at MPWLGCR[WL_SW_RES#].
18. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW_WL_EN] = 1
19. Repeates step 15-18 till the exact edge of CK was detected (i.e the write-leveling result switched from "0" to "1")
20. Issue MRS command to exit write leveling mode
21. Return the DQS output enable to functional mode by deasserting MDSCR[WL_EN]

44.11.7 Write fine tuning

"Write fine tuning is an additional circuit that provides the ability to fine tune the timing ofeach DQ/DM bits (relative to DQS) by up to 100 ps.This is done by selecting the number of delay units in each DQ/DM I/O (maximum 3 delay units of around 30-35 ps each). The delay can be configured independently for each DQ/DM. This configuration is controlled by the MPWRDQBY#DL register.

44.11.8 Read fine tuning

Read fine tuning is an additional circuit that provides the ability to fine tune the timing of each coming dq bits (relative to coming dqs) by up to +/-100 ps.

This is done by reducing the delay between the incoming rd_dqs by 100 ps and adding a configurable delay of up to 200 ps (6 delay units of around 30-35 ps each) for each DQ input. The delay can be configured independently for each DQ. The calibration of this mechanism can be done only by writing & reading data from the memory. Controlled by register MPRDDQBY#DL.

44.12 MMDC Memory Map/Register Definition

MMDC may be configured to several modes of operation. See Table 44-11 .

Table 44-11. MMDC - Modes of Operation

Mode of Operation	Abbreviation
DDR3 x16	DDR3_x16
DDR3 x32	DDR3_x32
DDR3 x64	DDR3_x64
LPDDR2 2-channels x16	LP2_2ch_x16
LPDDR2 2-channels x32	LP2_2ch_x32

NOTE

In case of LPDDR2 2-channels mode while the external memory devices are exactly the same for both channels then it is recommended to configure the registers located at 0x021B_0000 - 0x021B_0440 and 0x021B_4000 - 0x021B_4440 to the same values

In case of DDR3_x64 then IP port1 is used only to configure the parameters related to the calibration process of Byte4 - Byte7 at addresses 0x021B_4808 - 0x021B_48C0 as shown in Table 44-12 .

Table 44-12. MMDC - Modes of Operation

Mode of Operation	Associated Memory Map
DDR3 x16, x32	0x021B_0000 - 0x021B_08C4
DDR3 x64	0x021B_0000 - 0x021B_08C4 0x021B_4808 - 0x021B_48C0
LPDDR2 2-channels x16, x32	0x021B_0000 - 0x021B_08C4 0x021B_4808 - 0x021B_48C0

Table 44-13 shows the register mode of operations.

Table 44-13. Register Mode of Operations

Registers	1-Channel Mode of Operations	2-Channel Mode of Operations
MMDC Core Control Register	all	LP2_2ch_x16, LP2_2ch_x32
MMDC Core Power Down Control Register		all
MMDC Core ODT Timing Control Register		LP2_2ch_x16, LP2_2ch_x32
MMDC Core Timing Configuration Register 0		
MMDC Core Timing Configuration Register 1		
MMDC Core Timing Configuration Register 2		
MMDC Core Miscellaneous Register		
MMDC Core Special Command Register		
MMDC Core Refresh Control Register		
Reserved		all
Reserved		
MMDC Core Read/Write Command Delay Register		LP2_2ch_x16, LP2_2ch_x32
MMDC Core Out of Reset Delays Register		
MMDC Core MRR Data Register	LP2_2ch_x16, LP2_2ch_x32	LP2_2ch_x16, LP2_2ch_x32
MMDC Core Timing Configuration Register 3		LP2_2ch_x16, LP2_2ch_x32
MMDC Core MR4 Derating Register		
MMDC Core Address Space Partition Register	all	
MMDC Core AXI Reordering Control Regsiter		
MMDC Core Power Saving Control and Status Register		
MMDC Core Exclusive ID Monitor Register0		
MMDC Core Exclusive ID Monitor Register1		
MMDC Core Debug and Profiling Control Register 0		
MMDC Core Debug and Profiling Control Register 1		
MMDC Core Debug and Profiling Status Register 0		

Table continues on the next page...

Table 44-13. Register Mode of Operations (continued)

Registers	1-Channel Mode of Operations	2-Channel Mode of Operations
MMDC Core Debug and Profiling Status Register 1		
MMDC Core Debug and Profiling Status Register 2		
MMDC Core Debug and Profiling Status Register 3		
MMDC Core Debug and Profiling Status Register 4		
MMDC Core Debug and Profiling Status Register 5		
MMDC Core Step By Step Address Register		
MMDC Core Step By Step Address Attributes Register		
Reserved		all
MMDC Core General Purpose Register		LP2_2ch_x16, LP2_2ch_x32
MMDC PHY ZQ HW control register		all
MMDC PHY ZQ SW control register		
MMDC PHY Write Leveling Configuration and Error Status Register		DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Write Leveling Delay Control Register 0		
MMDC PHY Write Leveling Delay Control Register 1		DDR3_x64, LP2_2ch_x32
MMDC PHY Write Leveling delay-line Status Register		DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY ODT control register	DDR3_x16, DDR3_x32, DDR3_x64	DDR3_x64
MMDC PHY Read DQ Byte0 Delay Register	all	DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Read DQ Byte1 Delay Register		
MMDC PHY Read DQ Byte2 Delay Register		DDR3_x64, LP2_2ch_x32
MMDC PHY Read DQ Byte3 Delay Register		
MMDC PHY Write DQ Byte0 Delay Register		DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Write DQ Byte1 Delay Register		
MMDC PHY Write DQ Byte2 Delay Register		DDR3_x64, LP2_2ch_x32
MMDC PHY Write DQ Byte3 Delay Register		
MMDC PHY Read DQS Gating Control Register 0	DDR3_x16, DDR3_x32, DDR3_x64	DDR3_x64
MMDC PHY Read DQS Gating Control Register 1		
MMDC PHY Read DQS Gating delay-line Status Register		
MMDC PHY Read delay-lines Configuration Register	all	DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Read delay-lines Status Register		
MMDC PHY Write delay-lines Configuration Register		
MMDC PHY Write delay-lines Status Register		
MMDC PHY CK Control Register		LP2_2ch_x16, LP2_2ch_x32
MMDC ZQ LPDDR2 HW Control Register	LP2_2ch_x16, LP2_2ch_x32	
MMDC PHY Read Delay HW Calibration Control Register	all	DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Write Delay HW Calibration Control Register		
MMDC PHY Read Delay HW Calibration Status Register 0		
MMDC PHY Read Delay HW Calibration Status Register 1		DDR3_x64, LP2_2ch_x32

Table continues on the next page...

Table 44-13. Register Mode of Operations (continued)

Registers	1-Channel Mode of Operations	2-Channel Mode of Operations
MMDC PHY Write Delay HW Calibration Status Register 0		DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Write Delay HW Calibration Status Register 1		DDR3_x64, LP2_2ch_x32
MMDC PHY Write Leveling HW Error Register		DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Read DQS Gating HW Status Register 0	DDR3_x16, DDR3_x32, DDR3_x64	DDR3_x64
MMDC PHY Read DQS Gating HW Status Register 1		
MMDC PHY Read DQS Gating HW Status Register 2		
MMDC PHY Read DQS Gating HW Status Register 3		
MMDC PHY Pre-defined Compare Register 1	all	LP2_2ch_x16, LP2_2ch_x32
MMDC PHY Pre-defined Compare and CA delay-line Configuration Register		
MMDC PHY SW Dummy Access Register		DDR3_x64, LP2_2ch_x16, LP2_2ch_x32
MMDC PHY SW Dummy Read Data Register 0		
MMDC PHY SW Dummy Read Data Register 1		
MMDC PHY SW Dummy Read Data Register 2		
MMDC PHY SW Dummy Read Data Register 3		
MMDC PHY SW Dummy Read Data Register 4		
MMDC PHY SW Dummy Read Data Register 5		
MMDC PHY SW Dummy Read Data Register 6		
MMDC PHY SW Dummy Read Data Register 7		
MMDC PHY Measure Unit Register		LP2_2ch_x16, LP2_2ch_x32
MMDC Write CA delay-line controller	LP2_2ch_x16, LP2_2ch_x32	
MMDC Duty Cycle Control Register	all	DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Table 44-14 shows the maximum AXI address space for the main modes of operation.

Table 44-14. MMDC - Maximum AXI Address Space Per Operation Mode

Mode of Operation	Maximum AXI Address Space	Comment
LP2_2ch_x32	AXI port0: 0x8000_0000 - 0xFFFF_FFFFF	Up to 2GB for LPDDR2 Channel 0
	AXI port1: 0x1000_0000 - 0x7FFF_FFFFF	Up to 1.75GB for LPDDR2 Channel 1
DDR3_x64	AXI port0: 0x1000_0000 - 0xFFFF_FFFFF	All address space is associated with AXI port0

The Memory Map is shown below.

MMDC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
21B_0000	MMDC Core Control Register (MMDC1_MDCTL)	32	R/W	0311_0000h	44.12.1/ 3894
21B_0004	MMDC Core Power Down Control Register (MMDC1_MDPDC)	32	R/W	0003_0012h	44.12.2/ 3896
21B_0008	MMDC Core ODT Timing Control Register (MMDC1_MDOTC)	32	R/W	1227_2000h	44.12.3/ 3898
21B_000C	MMDC Core Timing Configuration Register 0 (MMDC1_MDCFG0)	32	R/W	3236_22D3h	44.12.4/ 3900
21B_0010	MMDC Core Timing Configuration Register 1 (MMDC1_MDCFG1)	32	R/W	B6B1_8A23h	44.12.5/ 3902

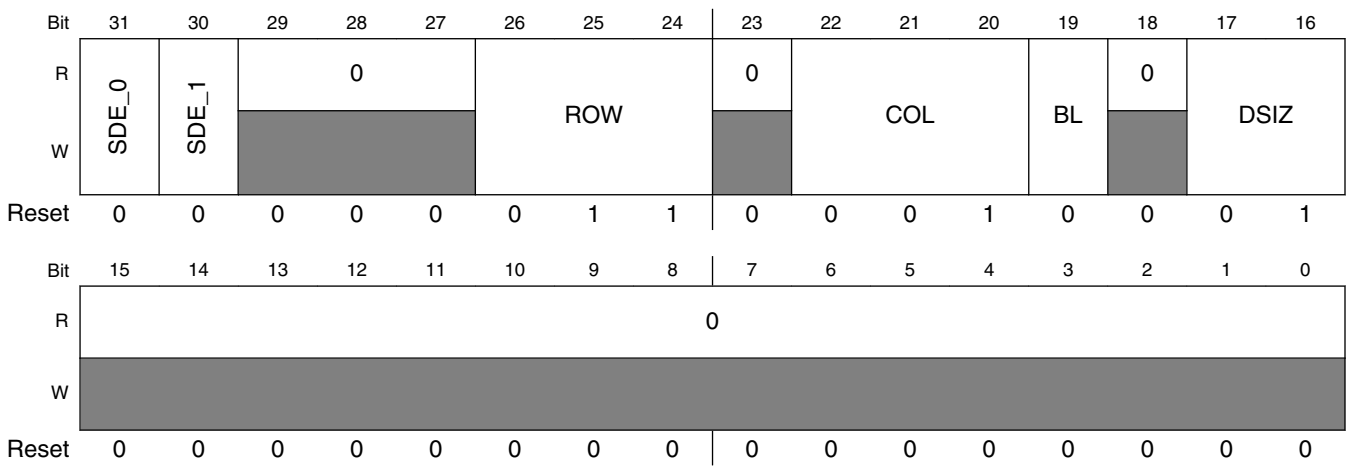
44.12.1 MMDC Core Control Register (MMDCx_MDCTL)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 0h offset



MMDCx_MDCTL field descriptions

Field	Description
31 SDE_0	MMDC Enable CS0. This bit enables/disables accesses from the MMDC toward Chip Select 0. The reset value of this bit is "0" (i.e No clocks and clock enable will be driven to the memory). At the enabling point the MMDC will perform an initialization process (including a delay on RESET and/or CKE) for both chip selects. The initialization length depends on the configured memory type. 0 Disabled 1 Enabled
30 SDE_1	MMDC Enable CS1. This bit enables/disables accesses from the MMDC toward Chip Select 1. The reset value of this bit is "0" (i.e No clocks and clock enable will be driven to the memory).

Table continues on the next page...

MMDCx_MDCTL field descriptions (continued)

Field	Description
	At the enabling point the MMDC will perform an initialization process (including a delay on RESET and/or CKE) for both chip selects. The initialization length depends on the configured memory type. 0 Disabled 1 Enabled
29–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 ROW	Row Address Width. This field specifies the number of row addresses used by the memory array. It will affect the way an incoming address will be decoded. Settings 110-111 are reserved 000 11 bits Row 001 12 bits Row 010 13 bits Row 011 14 bits Row 100 15 bits Row 101 16 bits Row
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–20 COL	Column Address Width. This field specifies the number of column addresses used by the memory array. It will determine how an incoming address will be decoded. 0x0 9 bits column 0x1 10 bits column 0x2 11 bits column 0x3 8 bits column 0x4 12 bits column 0x5-0xF Reserved
19 BL	Burst Length. This field determines the burst length of the DDR device. In LPDDR2 mode the MMDC supports burst length 4. In DDR3 mode the MMDC supports burst length 8. 0 Burst Length 4 is used 1 Burst Length 8 is used
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 DSIZ	DDR data bus size. This field determines the size of the data bus of the DDR memory 0 16-bit data bus 1 32-bit data bus — 2 64-bit data bus 3 Reserved —
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

44.12.2 MMDC Core Power Down Control Register (MMDCx_MDPDC)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Table 44-15. PRCT field encoding

PRCT[2:0]	Precharge Timer
000	Disabled (Bit field reset value)
001	2 clocks
010	4 clocks
011	8 clocks
100	16 clocks
101	32 clocks
110	64 clocks
111	128 clocks

Table 44-16. PWDT field encoding

PWDT[3:0]	Power Down Time-out
0000	Disabled (bit field reset value)
0001	16 cycles
0010	32 cycles
0011	64 cycles
0100	128 cycles
0101	256 cycles
0110	512 cycles
0111	1024 cycles
1000	2048 cycles
1001	4096 cycles
1010	8196 cycles
1011	16384 cycles
1100	32768 cycles
1101-1111	Reserved

Address: Base address + 4h offset

MMDCx_MDPDC field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–28 PRCT_1	Precharge Timer - Chip Select 1. This field determines the amount of idle cycle for which chip select 1 will be automatically precharged. The amount of cycles are determined according to the PRCT Field Encoding table above.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 PRCT_0	Precharge Timer - Chip Select 0. This field determines the amount of idle cycle for which chip select 0 will be automatically precharged. The amount of cycles are determined according to the table below.
23–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 tCKE	CKE minimum pulse width. This field determines the minimum pulse width of CKE. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
15–12 PWDT_1	Power Down Timer - Chip Select 1. This field determines the amount of idle cycle for which chip select 1 will be automatically get into precharge/active power down. The amount of cycles are determined according to the PWDT Field Encoding table above.
11–8 PWDT_0	Power Down Timer - Chip Select 0. This field determines the amount of idle cycle for which chip select 0 will be automatically get into precharge/active power down. The amount of cycles are determined according to the PWDT Field Encoding table above.
7 SLOW_PD	Slow/fast power down. In DDR3 mode this field is referred to slow precharge power-down. In LPDDR2 mode this field is not relevant.

Table continues on the next page...

MMDCx_MDPDC field descriptions (continued)

Field	Description
	NOTE: Memory should be configured the same. 0 Fast mode. 1 Slow mode.
6 BOTH_CS_PD	Parallel power down entry to both chip selects. When power down timer is used for both chip-selects (i.e PWDT_0 and PWDT1 don't equal "0") , then if this bit is enabled, the MMDC will enter power down only if the amount of idle cycles of both chip selects was obtained. 0 Each chip select can enter power down independently according to its configuration. 1 Chip selects can enter power down only if the amount of idle cycles of both chip selects was obtained.
5–3 tCKSRX	Valid clock cycles before self-refresh exit. This field determines the amount of clock cycles before self-refresh exit 0x0 0 cycle 0x1 1 cycles 0x6 6 cycles 0x7 7 cycles
tCKSRE	Valid clock cycles after self-refresh entry. This field determines the amount of clock cycles after self-refresh entry 0x0 0 cycle 0x1 1 cycles 0x6 6cycles 0x7 7cycles

44.12.3 MMDC Core ODT Timing Control Register (MMDCx_MDOTC)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

For further information see ODT Configuration .

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MMDCx_MDOTC field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–27 tAOFPD	Asynchronous RTT turn-off delay (power down with DLL frozen). This field determines the time between termination cuircuit starts to turn off the ODT resistance till termination has reached high impedance. This field is not relevant in LPDDR2 mode. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
26–24 tAONPD	Asynchronous RTT turn-on delay (power down with DLL frozen). This field determines the time between termination cuircuit gets out of high impedance and begins to turn on till ODT resistance are fully on. This field is not relevant in LPDDR2 mode. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
23–20 tANPD	Asynchronous ODT to power down entry delay. In DDR3 should be set to tCWL-1 This field is not relevant in LPDDR2 mode. 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF 16 clocks
19–16 tAXPD	Asynchronous ODT to power down exit delay. In DDR3 should be set to tCWL-1 This field is not relevant in LPDDR2 mode. 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF 16 clocks
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–12 tODTLon	ODT turn on latency. This field determines the delay between ODT signal and the associated RTT, where according to JEDEC standard it equals WL(write latency) - 2. Therefore, the value that is configured to tODTLon field should correspond the value that is configured to MDCGFG1[tCWL] In LPDDR2 this field is not relevant. 0x0 - 0x1 Reserved 0x2 2 cycles 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles

Table continues on the next page...

MMDCx_MDOTC field descriptions (continued)

Field	Description
	0x6 6 cycles 0x7 Reserved
11–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–4 tODT_idle_off	ODT turn off latency. This field determines the Idle period before turning memory ODT off. This field is not relevant in LPDDR2 mode. 0x0 0 cycle (turned off at the earliest possible time) 0x1 1 cycle 0x2 2 cycles 0x1E 30 cycles 0x1F 31 cycles
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

44.12.4 MMDC Core Timing Configuration Register 0 (MMDCx_MDCFG0)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

44.12.7 MMDC Core Miscellaneous Register (MMDCx_MDMISC)

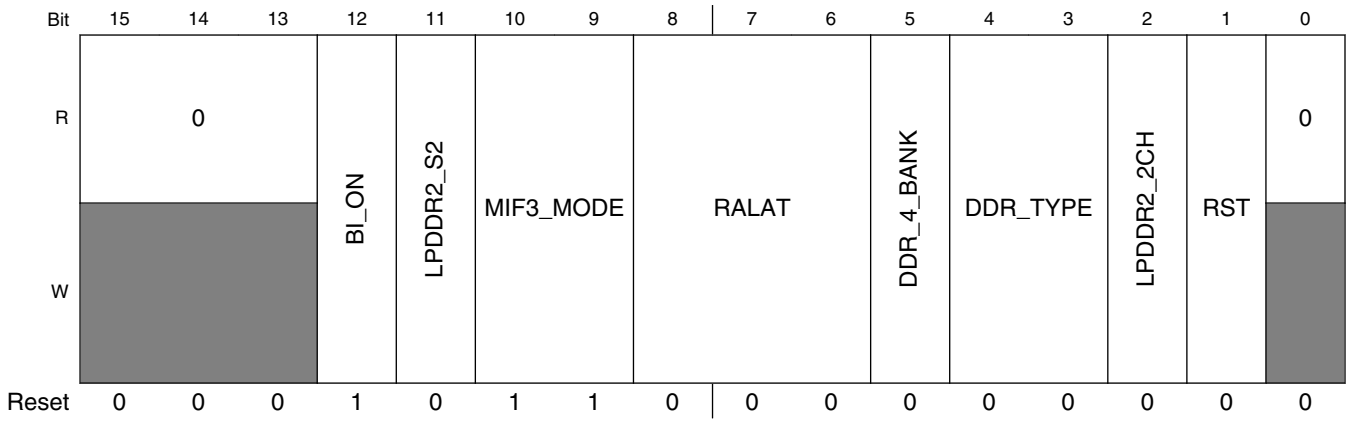
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CS0_RDY	CS1_RDY	0									CALIB_PER_CS	ADDR_MIRROR	LHD	WALAT	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



MMDCx_MDMISC field descriptions

Field	Description
31 CS0_RDY	External status device on CS0. This is a read-only status bit, that indicates whether the external memory is in wake-up period. 0 Device in wake-up period. 1 Device is ready for initialization.
30 CS1_RDY	External status device on CS1. This is a read-only status bit, that indicates whether the external memory is in wake-up period. 0 Device in wake-up period. 1 Device is ready for initialization.
29–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 CALIB_PER_CS	Number of chip-select for calibration process. This bit determines the chip-select index that the associated calibration is targetted to. Relevant for read, write, write leveling and read DQS gating calibrations 0 Calibration is targetted to CS0 1 Calibration is targetted to CS1
19 ADDR_MIRROR	Address mirroring. **NOTE:** This feature is not supported for LPDDR2 memories. But only for DDR3 memories. For further information see Address mirroring . 0 Address mirroring disabled. 1 Address mirroring enabled.
18 LHD	Latency hiding disable. This is a debug feature. When set to "1" the MMDC will handle one read/write access at a time. Meaning that the MMDC pipe-line will be limitted to 1 open access (next AXI address phase will be acknowledged if the current AXI data phase had finished) 0 Latency hiding on. 1 Latency hiding disable.
17–16 WALAT	Write Additional latency. In case the write-leveling calibration process indicates a delay of greater than one-eighth a clock cycle (between CK and any of the DQS strobe lines), then this field must be configured accordingly.

Table continues on the next page...

MMDCx_MDMISC field descriptions (continued)

Field	Description
	This field will add delay on the obe I/O control, which will compensate on the additional write leveling delay on DQS and prevent the DQS from being cropped. **NOTE:** The purpose of WALAT is to add time delay at the end of a burst write operation to ensure that the JEDEC time specification for Write Post Amble Delay (tWPST) is met (DQS strobe is held low at the end of a write burst for > 30% a clock cycle before it is released). If the value of any of the WL_DL_ABS_OFFSETn register fields are greater than '1F', WALAT should be set to '1' (cycle additional delay). WALAT should be further increased for any full cycle delays added by the WL_CYC_DELn register fields. 0x0 No additional latency required. 0x1 1 cycle additional delay 0x2 2 cycles additional delay 0x3 3 cycles additional delay
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 BI_ON	Bank Interleaving On. This bit controls the organization of the bank, row and column address bits. For further information see Address decoding . 0 Banks are not interleaved, and address will be decoded as bank-row-column 1 Banks are interleaved, and address will be decoded as row-bank-column
11 LPDDR2_S2	LPDDR2 S2 device type indication. In case LPDDR2 device is used (DDR_TYPE = 0x1), this bit will indicate whether S2 or S4 device is used. This bit should be cleared in DDR3 mode 0x0 LPDDR2-S4 device is used. 0x1 LPDDR2-S2 device is used.
10–9 MIF3_MODE	Command prediction working mode. This field determines the level of command prediction that will be used by the MMDC 00 Disable prediction. 01 Enable prediction based on : Valid access on first pipe line stage. 10 Enable prediction based on: Valid access on first pipe line stage, Valid access on axi bus. 11 Enable prediction based on: Valid access on first pipe line stage, Valid access on axi bus, Next miss access from access queue.
8–6 RALAT	Read Additional Latency. This field determines the additional read latency which is added to CAS latency and internal delays for which the MMDC will retrieve the read data from the internal FIFO. This field is used to compensate on board/chip delays. **NOTE:** In LPDDR2 mode 2 extra cycles will be added internally in order to compensate tDQSCK delay. 0x0 no additional latency. 0x1 1 cycle additional latency. 0x2 2 cycles additional latency. 0x3 3 cycles additional latency. 0x4 4 cycles additional latency. 0x5 5 cycles additional latency. 0x6 6 cycles additional latency. 0x7 7 cycles additional latency.

Table continues on the next page...

MMDCx_MDMISC field descriptions (continued)

Field	Description
5 DDR_4_BANK	Number of banks per DDR device. When this bit is set to "1" then the MMDC will work with DDR device of 4 banks. 0 8 banks device is being used. (Default) 1 4 banks device is being used
4–3 DDR_TYPE	DDR TYPE. This field determines the type of the external DDR device. 0x0 DDR3 device is used. (Default) 0x1 LPDDR2 device is used. — — 0x2 Reserved. 0x3 Reserved.
2 LPDDR2_2CH	LPDDR2 2-channels mode. When this bit is set to "1" then dual channel mode is activated. This field should be cleared for DDR3 mode. 0 1-channel mode (DDR3) 1 2-channels mode (LPDDR2)
1 RST	Software Reset. When this bit is asserted then the internal FSMs and registers of the MMDC will be initialized. **NOTE:** This bit once asserted gets deasserted automatically. 0 Do nothing. 1 Assert reset to the MMDC.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

44.12.8 MMDC Core Special Command Register (MMDCx_MDSCR)

This register is used to issue special commands manually toward the external DDR device (such as load mode register, manual self refresh, manual precharge and so on). Every write to this register will be interpreted as a command, and a read from this register will show the last command that was executed.

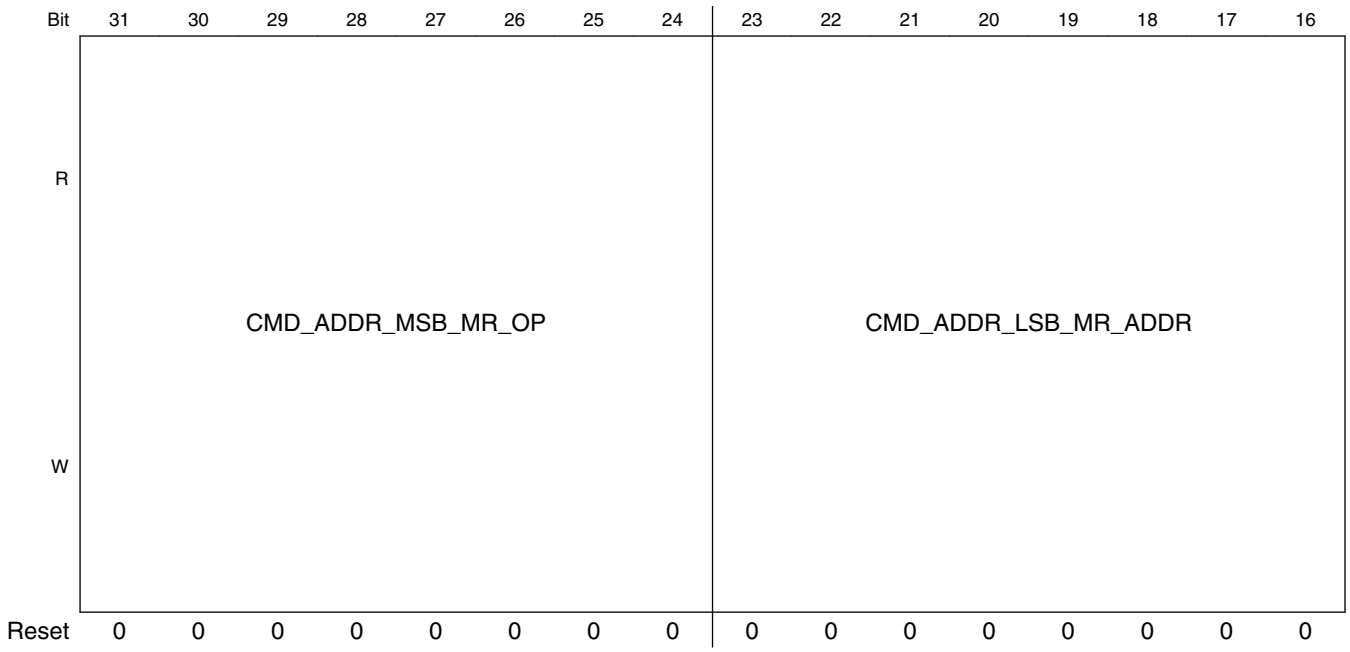
Every write to this register will result in one special command, and the IP bus will assert ips_xfr_wait as long as the special command is being carried out.

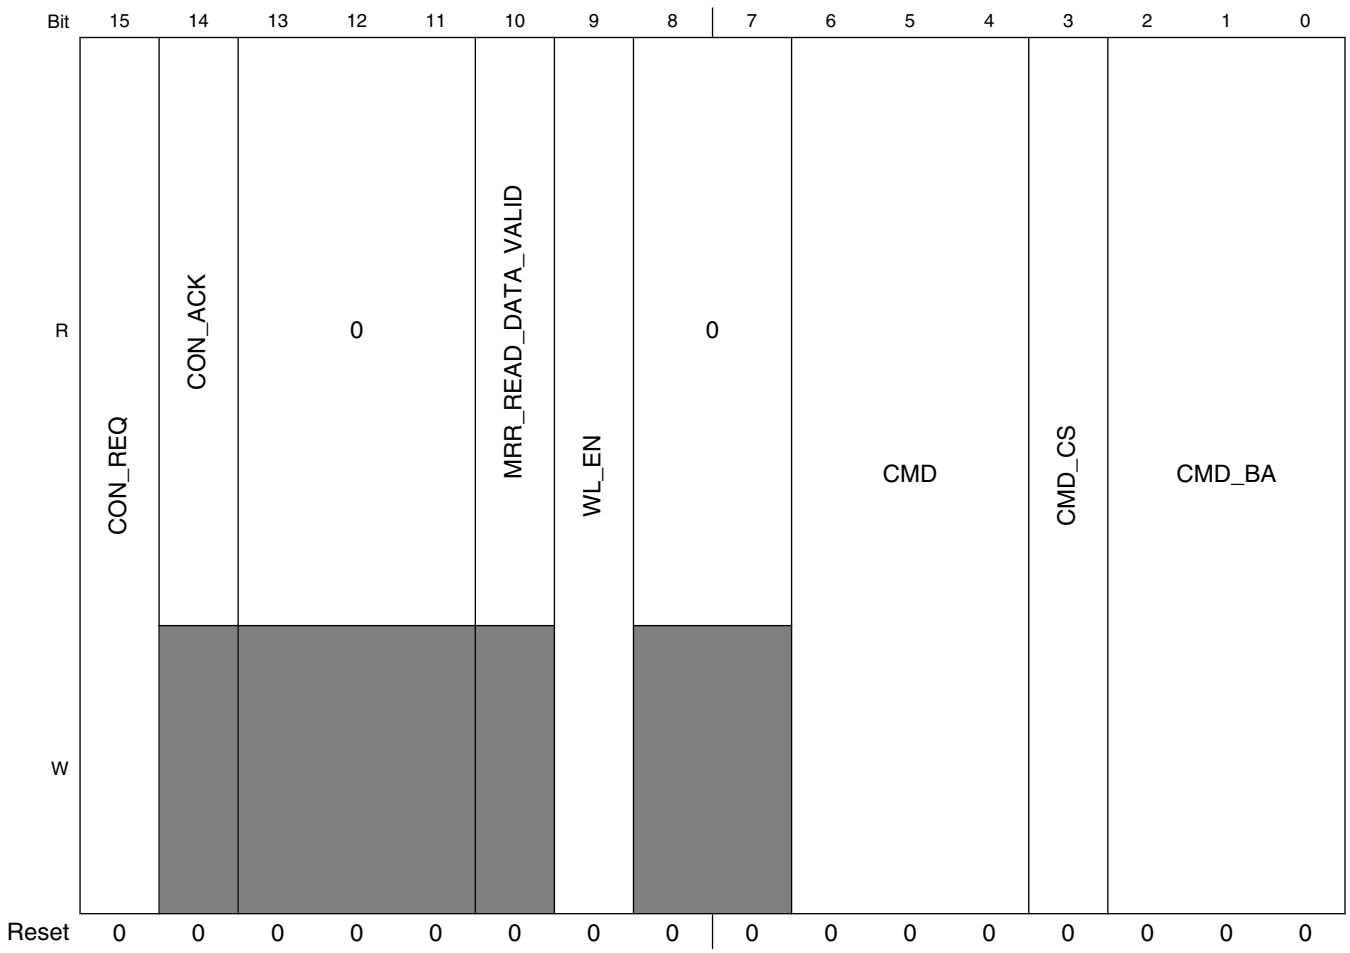
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 1Ch offset





MMDCx_MDSCR field descriptions

Field	Description
31–24 CMD_ADDR_ MSB_MR_OP	Command/Address MSB. This field indicates the MSB of the command/Address. In LPDDR2 this field indicates the MRW operand
23–16 CMD_ADDR_ LSB_MR_ADDR	Command/Address LSB. This field indicates the LSB of the command/Address In LPDDR2 this field indicates the MRR/MRW address
15 CON_REQ	Configuration request. When this bit is set then the MMDC will clean the pending AXI accesses and will prevent from further AXI accesses to be acknowledged. This field guarantee safe configuration (or change configuration) of the MMDC while no access is in process and prevents an unexpected behaviour. After setting this bit, it is needed to poll on CON_ACK until it is set to "1". When CON_ACK is asserted then configuration is permitted. After configuration is completed then this bit must be deasserted in order to process further AXI accesses. **NOTE:** This bit is asserted at the end of the reset sequence, meaning that the MMDC is waiting to configure and intialize the external memory before accepting any AXI accesses. Configuration request/acknowledge mechanism should be used for the following procedures: changing of timing parameters , during calibration process or driving commands via MDSCR[CMD] 0 No request to configure MMDC. 1 A request to configure MMDC is valid
14 CON_ACK	Configuration acknowledge. Whenever this bit is set, it is permitted to configure MMDC IP registers. 0 Configuration of MMDC registers is forbidden. 1 Configuration of MMDC registers is permitted.
13–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 MRR_READ_ DATA_VALID	MRR read data valid. This field indicates that read data is valid at MDMRR register This field is relevant only for LPDDR2 mode 0 Cleared upon the assertion of MRR command 1 Set after MRR data is valid and stored at MDMRR register.
9 WL_EN	DQS pads direction. This bit controls the DQS pads direction during write-leveling calibration process. Before starting the write-leveling calibration process this bit should be set to "1". It should be set to "0" when sending write leveling exit command. For further information see Write leveling Calibration . 0 Exit write leveling mode or stay in normal mode. 1 Write leveling entry command was sent.
8–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 CMD	Command. This field contains the command to be executed. This field will be automatically cleared after the command will be send to the DDR memory. 0x0 Normal operation 0x1 Precharge all, command is sent independently of bank status (set correct CMD_CS). Will be issued even if banks are closed. Mainly used for init sequence purpose.

Table continues on the next page...

MMDCx_MDSCR field descriptions (continued)

Field	Description
	0x2 Auto-Refresh Command (set correct CMD_CS). 0x3 Load Mode Register Command (DDR3, set correct CMD_CS, CMD_BA, CMD_ADDR_LSB, CMD_ADDR_MSB), MRW Command (LPDDR2, set correct CMD_CS, MR_OP, MR_ADDR) 0x4 ZQ calibration (DDR3, set correct CMD_CS, {CMD_ADDR_MSB,CMD_ADDR_LSB} = 0x400 or 0x0) 0x5 Precharge all, only if banks open (set correct CMD_CS). 0x6 MRR command (LPDDR2, set correct CMD_CS, MR_ADDR) 0x7 Reserved
3 CMD_CS	Chip Select. This field determines which chip select the command is targeted to 0 to Chip-select 0 1 to Chip-select 1
CMD_BA	Bank Address. This field determines the address of the bank within the selected chip-select where the command is targetted to. 0x0 bank address 0 0x1 bank address 1 0x2 bank address 2 0x7 bank address 7

44.12.9 MMDC Core Refresh Control Register (MMDCx_MDREF)

This register determines the refresh scheme that will be executed toward the DDR device. It specifies how often a refresh cycle occurs and how many refresh commands will be executed every refresh cycle.

For further information see Refresh Scheme .

The following tables show examples of possible refresh schemes.

Table 44-17. Refresh rate example for REF_SEL = 0

REFR[2:0]	Number of refresh commands every 64KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	15.6 µs	tRFC
0x1	2	7.8 µs	2*tRFC
0x3	4	3.9µs	4*tRFC
0x7	8	1.95 µs	8*tRFC

Table 44-18. Refresh rate example for REF_SEL = 1

REFR[2:0]	Number of refresh commands every 32KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x1	2	15.6 µs	2*tRFC
0x3	4	7.8 µs	4*tRFC
0x7	8	3.9µs	8*tRFC

Table 44-19. Refresh rate example for REF_SEL = 2@ 400MHz

REFR[2:0]	Number of refresh commands every refresh cycle	REF_CNT	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	0x618	3.9 µs	tRFC
0x1	2	0xC30	3.9 µs	2*tRFC
0x2	3	0x1248	3.9µs	3*tRFC
0x3	4	0x1860	3.9 µs	4*tRFC

Other refresh configurations are also allowed; the configuration values in the tables above are only examples for obtaining the desired average periodic refresh rate.

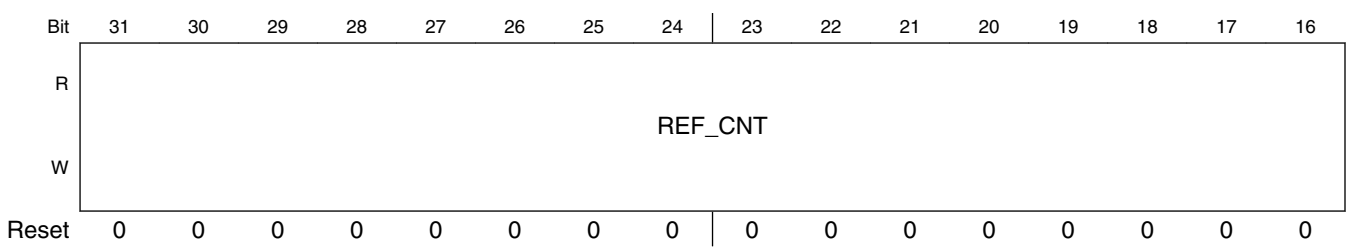
If the required average periodic refresh rate (tREFI) is kept, all of the rows will be refreshed in every refresh window. Because the memory device issues additional refresh commands for every refresh it receives, the tREFI remains the same across the device, regardless of its number of rows. This is particularly relevant in the tRFC parameter, which becomes bigger as the density increases.

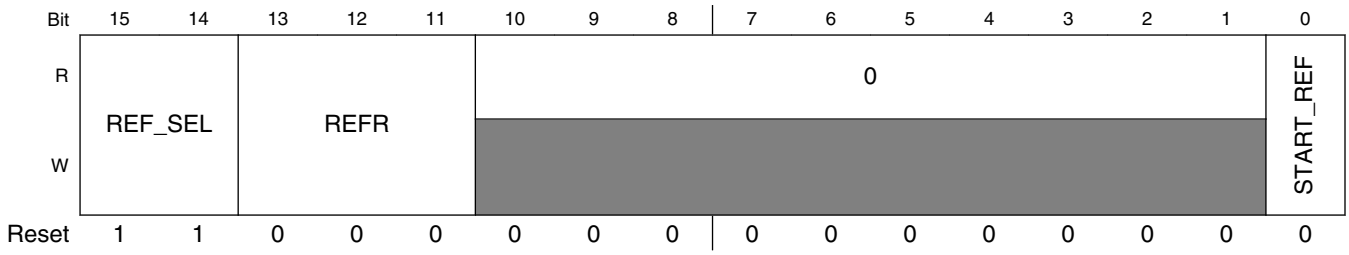
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 20h offset





MMDCx_MDREF field descriptions

Field	Description
31–16 REF_CNT	Refresh Counter at DDR clock period If REF_SEL equals '2' a refresh cycle will begin every amount of DDR cycles configured in this field. 0x0 Reserved. 0x1 1 cycle. 0xFFFE 65534 cycles. 0xFFFF 65535 cycles.
15–14 REF_SEL	Refresh Selector. This bit selects the source of the clock that will trigger each refresh cycle: 0 Periodic refresh cycles will be triggered in frequency of 64KHz. 1 Periodic refresh cycles will be triggered in frequency of 32KHz. 2 Periodic refresh cycles will be triggered every amount of cycles that are configured in REF_CNT field. 3 No refresh cycles will be triggered.
13–11 REFR	Refresh Rate. This field determines how many refresh commands will be issued every refresh cycle. After every refresh command the MMDC won't drive any command to the DDR device untill satisfying tRFC period 0x0 1 refresh 0x1 2 refreshes 0x2 3 refreshes 0x3 4 refreshes 0x4 5 refreshes 0x5 6 refreshes 0x6 7 refreshes 0x7 8 refreshes
10–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 START_REF	Manual start of refresh cycle. When this field is set to '1' the MMDC will start a refresh cycle immediately according to number of refresh commands that are configured in 'REFR' field. This bit returns to zero automatically. 0 Do nothing. 1 Start a refresh cycle.

44.12.10 MMDC Core Read/Write Command Delay Register (MMDCx_MDRWD)

This register determines the delay between back to back read and write accesses. The register reset values are set to the minimum required value. As the default values are set to achieve optimal results, changing them is discouraged.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 2Ch offset

	0x5 5 cycles 0x6 6 cycles 0x7 7 cycles

44.12.11 MMDC Core Out of Reset Delays Register (MMDCx_MDOR)

This register defines delays that must be kept when MMDC exits reset.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								tXPR								0		SDE_to_RST						0		RST_to_CKE					
W																																
Reset	0	0	0	0	0	0	0	0	1	0	0	1	1	1	1	1	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1	0

MMDCx_MDOR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 tXPR	DDR3: CKE HIGH to a valid command. LPDDR2: Not relevant to this mode. Please leave in default reset value. DDR3: As defined in timing parameter table. 0x0 Reserved 0x1 2 cycles 0x2 3 cycles 0xFE 255 cycles 0xFF 256 cycles
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–8 SDE_to_RST	DDR3: Time from SDE enable until DDR reset# is high. In LPDDR2 mode this field is not relevant . **NOTE:** Each cycle in this field is 15.258 us. 0x0 Reserved 0x1 Reserved

Table continues on the next page...

MMDCx_MDOR field descriptions (continued)

Field	Description
	0x2 Reserved 0x3 1 cycles 0x4 2 cycles 0x10 14 cycles (Jedec value for DDR3) - total of 200 us 0x3E 60 cycles 0x3F 61 cycles
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RST_to_CKE	DDR3: Time from SDE enable to CKE rise. In case that DDR reset# is low, will wait until it's high and thenwait this period until rising CKE. (JEDEC value is 500 us) LPDDR2: Idle time ater first CKE assertion. (JEDEC value is 200 us) **NOTE:** Each cycle in this field is 15.258 us. 0x0 Reserved 0x1 Reserved 0x2 Reserved 0x3 1 cycles 0x10 14 cycles (JEDEC value for LPDDR2) - total of 200 us 0x23 33 cycles (JEDEC value for DDR3) - total of 500 us 0x3E 60 cycles 0x3F 61 cycles

44.12.12 MMDC Core MRR Data Register (MMDCx_MDMRR)

This register contains data that was collected after issuing MRR command. The data in this register is valid only when MDSCR[MRR_READ_DATA_VALID] is set to "1".

This register is relevant only in LPDDR2 mode. For further information see LPDDR2 Refresh Rate Update and Timing Derating .

Supported Mode Of Operations:

For Channel 0: LP2_2ch_x16, LP2_2ch_x32

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 34h offset

Bit	31–24	23–16	15–8	7–0
R	MRR_READ_DATA3	MRR_READ_DATA2	MRR_READ_DATA1	MRR_READ_DATA0
W				
Reset	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

MMDCx_MDMRR field descriptions

Field	Description
31–24 MRR_READ_DATA3	MRR DATA that arrived on DQ[31:24]
23–16 MRR_READ_DATA2	MRR DATA that arrived on DQ[23:16]
15–8 MRR_READ_DATA1	MRR DATA that arrived on DQ[15:8]
MRR_READ_DATA0	MRR DATA that arrived on DQ[7:0]

44.12.13 MMDC Core Timing Configuration Register 3 (MMDCx_MDCFG3LP)

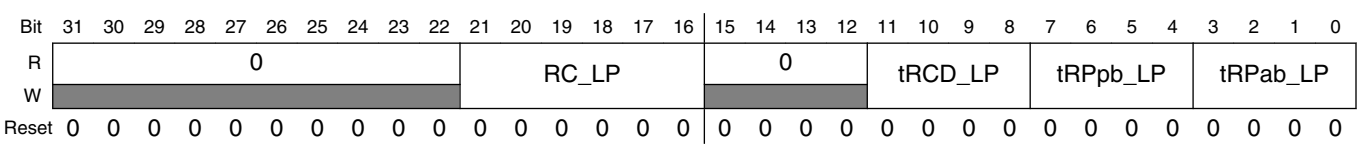
This register is relevant only for LPDDR2 mode.

Supported Mode Of Operations:

For Channel 0: LP2_2ch_x16, LP2_2ch_x32

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 38h offset



MMDCx_MDCFG3LP field descriptions

Field	Description
31–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 RC_LP	Active to Active or Refresh command period (same bank). (This field is valid only for LPDDR2 memories) 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0x3E 63 clocks 0x3F Reserved
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MMDCx_MDCFG3LP field descriptions (continued)

Field	Description
11–8 tRCD_LP	Active command to internal read or write delay time (same bank). (This field is valid only for LPDDR2 memories) 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved
7–4 tRPpb_LP	Precharge (per bank) command period (same bank). (This field is valid only for LPDDR2 memories) 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved
tRPab_LP	Precharge (all banks) command period. (This field is valid only for LPDDR2 memories) 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved

44.12.14 MMDC Core MR4 Derating Register (MMDCx_MDMR4)

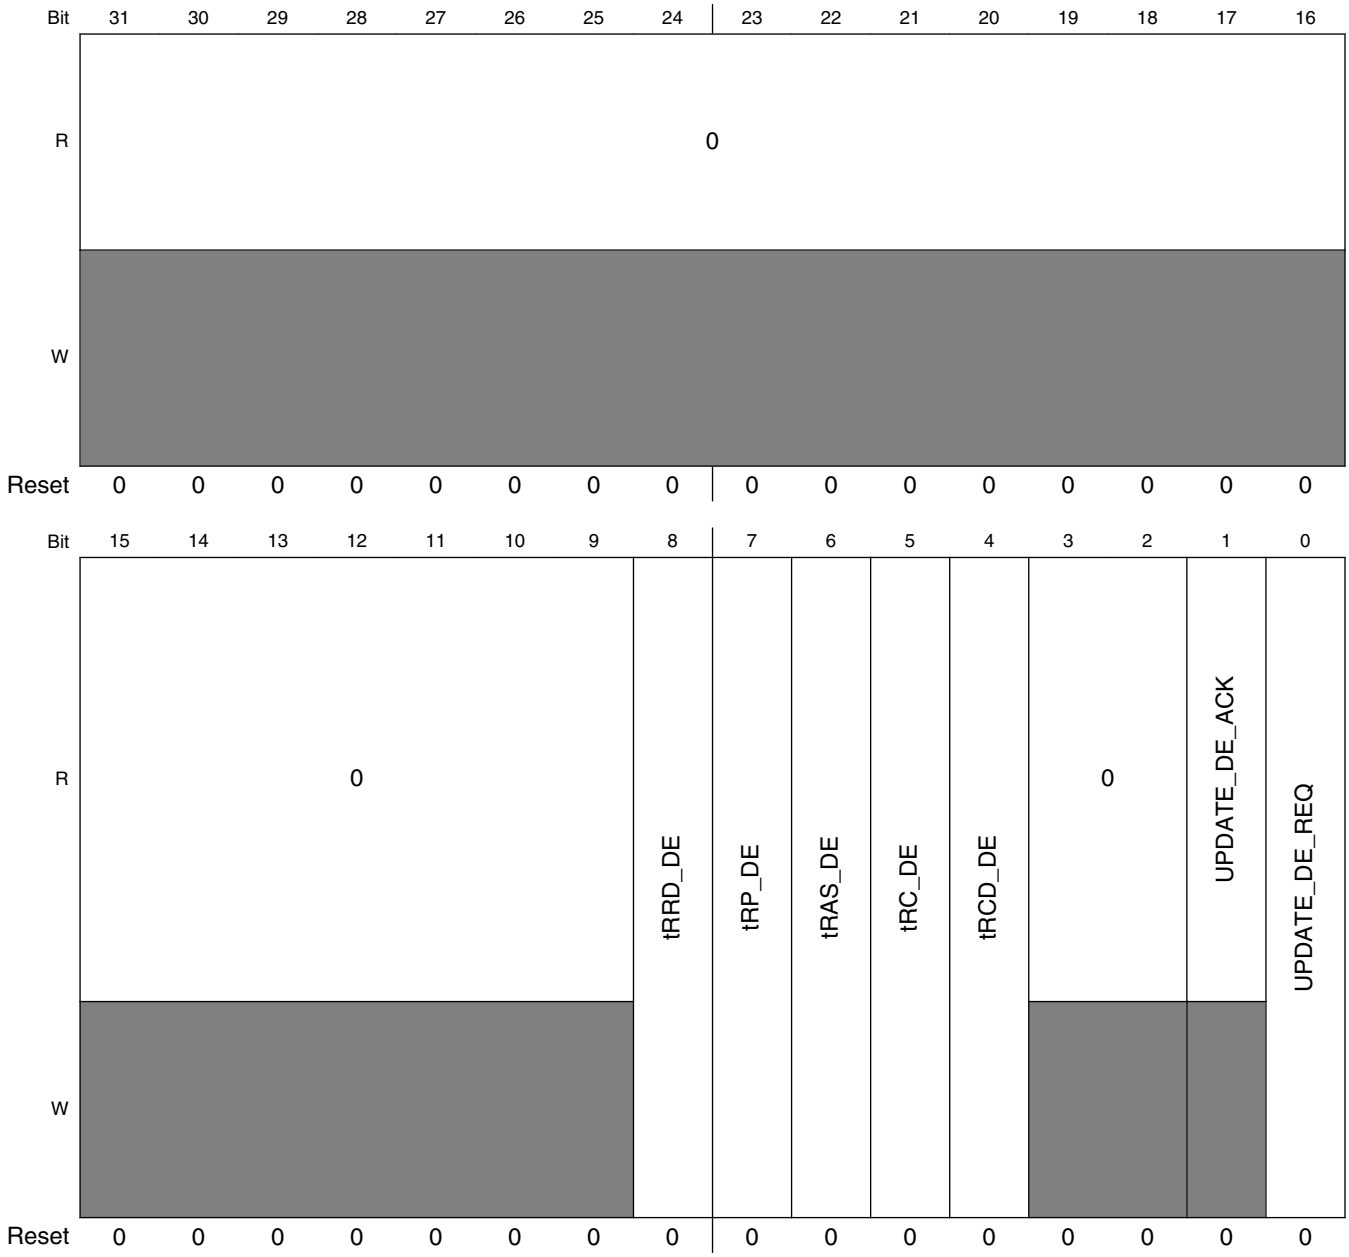
This register is relevant only for LPDDR2 mode. It is used to dynamically change certain values depending on MR4 read result, which is based on memory temperature sensor result.

Supported Mode of Operations:

For Channel 0: LP2_2ch_x16, LP2_2ch_x32

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 3Ch offset



MMDCx_MDMR4 field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 tRRD_DE	tRRD derating value. 0 Original tRRD is used. 1 tRRD is derated in 1 cycle.
7 tRP_DE	tRP derating value.

Table continues on the next page...

MMDCx_MDMR4 field descriptions (continued)

Field	Description
	0 Original tRP is used. 1 tRP is derated in 1 cycle.
6 tRAS_DE	tRAS derating value. 0 Original tRAS is used. 1 tRAS is derated in 1 cycle.
5 tRC_DE	tRC derating value. 0 Original tRC is used. 1 tRC is derated in 1 cycle.
4 tRCD_DE	tRCD derating value. 0 Original tRCD is used. 1 tRCD is derated in 1 cycle.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 UPDATE_DE_ACK	Update Derated Values Acknowledge. This read only bit will be cleared upon UPDATE_DE_REQ assertion and will be set after the new values are taken.
0 UPDATE_DE_REQ	Update Derated Values Request. This read modify write field is automatically cleared after the request is issued. 0 Do nothing. 1 Request to update the following values: tRRD, tRCD, tRP, tRC, tRAS and refresh related fields(MDREF register): REF_CNT, REF_SEL, REFR

44.12.15 MMDC Core Address Space Partition Register (MMDCx_MDASP)

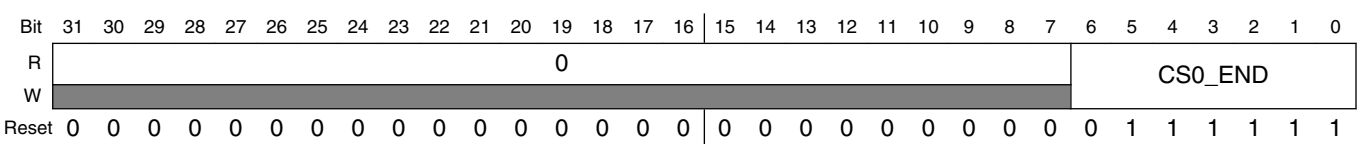
This register defines the partitioning between chip select 0 and chip select 1. For further information see Chip select settings .

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 40h offset



MMDCx_MDASP field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CS0_END	CS0_END. Defines the absolute last address associated with CS0 with increments of 256Mb. CS0_END=AXI_ADDRESS[31:25] bits. In DDR3 and 1-channel LPDDR2 mode: MMDCx_MDASP[CS0_END] should be set to DDR_CS_SIZE/32MB + 0x7 (DDR base address begins at 0x10000000) In 2-channel LPDDR2 mode: MMDC0_MDASP[CS0_END] should be set to DDR_CS_SIZE/32M + 0x3f (channel 0 base address begins at 0x80000000) MMDC1_MDASP[CS0_END] should be set to DDR_CS_SIZE/32M + 0x7 (channel 1 base address begins at 0x10000000) In 2-channel LPDDR2 with 4k-interleave mode: MMDC0_MDASP[CS0_END] should be set to DDR_CS_SIZE/32M + 0x43 MMDC1_MDASP[CS0_END] should be set to DDR_CS_SIZE/32M + 0x3

44.12.16 MMDC Core AXI Reordering Control Register (MMDCx_MAARCR)

This register determines the values of the weights used for the re-ordering arbitration engine. For further information see Performance .

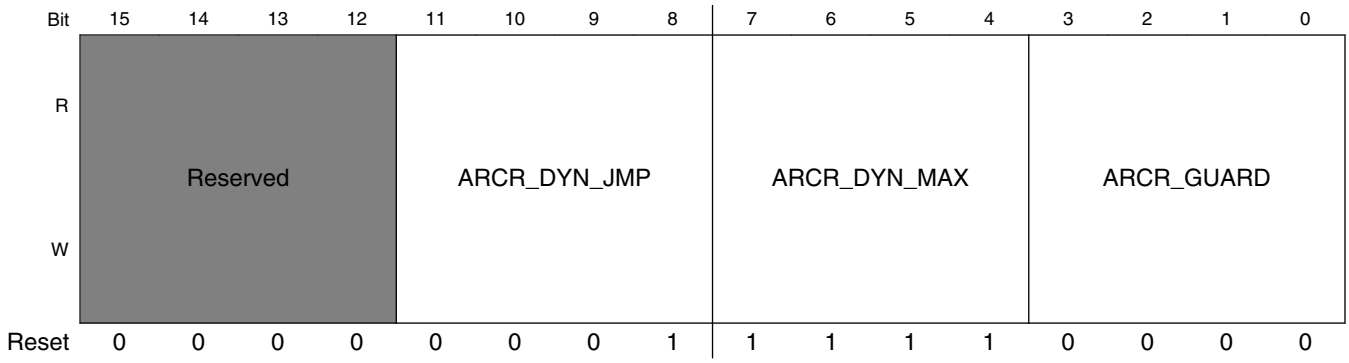
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 400h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ARCR_SEC_ERR_LOCK	ARCR_SEC_ERR_EN	Reserved	ARCR_EXC_ERR_EN	Reserved			ARCR_RCH_EN	Reserved	ARCR_PAG_HIT			Reserved	ARCR_ACC_HIT		
Reset	0	1	0	1	0	0	0	1	0	1	0	0	0	0	1	0



MMDCx_MAARCR field descriptions

Field	Description
31 ARCR_SEC_ERR_LOCK	Once set, this bit locks ARCR_SEC_ERR_EN and prevents from its updating. This bit can be only cleared by reset Default value is 0x0 - encoding 0 (unlocked) 0 ARCR_SEC_ERR_EN is unlocked, so can be updated any moment 1 ARCR_SEC_ERR_EN is locked, so it can't be updated
30 ARCR_SEC_ERR_EN	This bit defines whether security read/write access violation result in SLV Error response or in OKAY response Default value is 0x1 - encoding 1(response is SLV Error, rresp/bresp=2'b10) 0 security violation results in OKAY response (rresp/bresp=2'b00) 1 security violation results in SLAVE Error response (rresp/bresp=2'b10)
29 Reserved	This field is reserved. Reserved
28 ARCR_EXC_ERR_EN	This bit defines whether exclusive read/write access violation of AXI 6.2.4 rule result in SLV Error response or in OKAY response Default value is 0x1 - encoding 1(response is SLV Error) 0 violation of AXI exclusive rules (6.2.4) result in OKAY response (rresp/bresp=2'b00) 1 violation of AXI exclusive rules (6.2.4) result in SLAVE Error response (rresp/bresp=2'b10)
27–25 Reserved	This field is reserved. Reserved
24 ARCR_RCH_EN	This bit defines whether Real time channel is activated and bypassed all other pending accesses, So accesses with QoS=='F' will be granted the highest priority in the optimization/reordering mechanism Default value is 0x1 - encoding 1 (Enabled) 0 normal prioritization, no bypassing 1 accesses with QoS=='F' bypass the arbitration
23 Reserved	This field is reserved. Reserved
22–20 ARCR_PAG_HIT	ARCR Page Hit Rate. This value will be added by the optimization/reordering mechanism to any pending access that is targeted to an open DDR row. Default value of ARCR_PAG_HIT is 0x00100 - encoding 4.
19 Reserved	This field is reserved. Reserved

Table continues on the next page...

MMDCx_MAARCR field descriptions (continued)

Field	Description
18–16 ARCR_ACC_HIT	ARCR Access Hit Rate. This value will be added by the optimization/reordering mechanism to any pending access that has the same access type (read/write) as the previous access. Default value of is ARCR_ACC_HIT 0x0010 - encoding 2.
15–12 Reserved	This field is reserved. Reserved
11–8 ARCR_DYN_JMP	ARCR Dynamic Jump. Each time an access wan't chosen by the optimization/reordering mechanism then its dynamic score will be incremented by ARCR_DYN_JMP value. **NOTE:** Setting ARCR_DYN_JMP may cause starvation of low priority accesses **NOTE:** ARCR_DYN_JMP must be smaller than ARCR_DYN_MAX Default ARCR_DYN_JMP value is 0x0001 - encoding 1
7–4 ARCR_DYN_MAX	ARCR Dynamic Maximum. ARCR_DYN_MAX is the maximum dynamic score value that each access inside the optimization/reordering mechanism can get. 0000 0 0001 1 1111 15 (default)
ARCR_GUARD	ARCR Guard. After an access reached the maximum dynamic score value, it will wait additional ARCR_GUARD arbitration cycles and then will gain the highest priority in the optimization/reordering mechanism. 0000 15 (default) 0001 16 1111 30

44.12.17 MMDC Core Power Saving Control and Status Register (MMDCx_MAPSR)

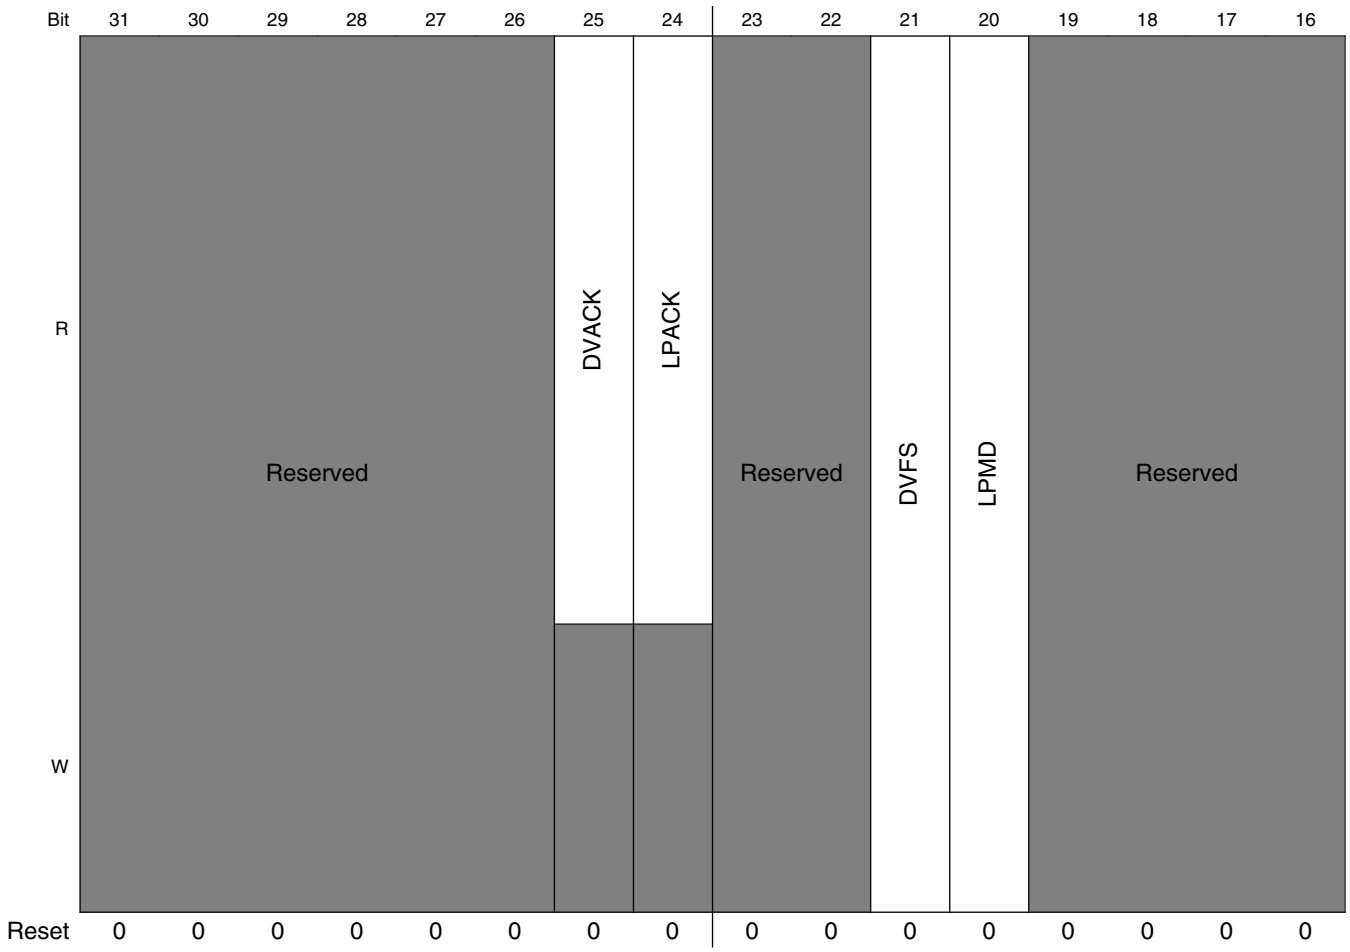
The MAPSR determines the power saving features of MMDC. For further information see Power Saving and Clock Frequency Change modes .

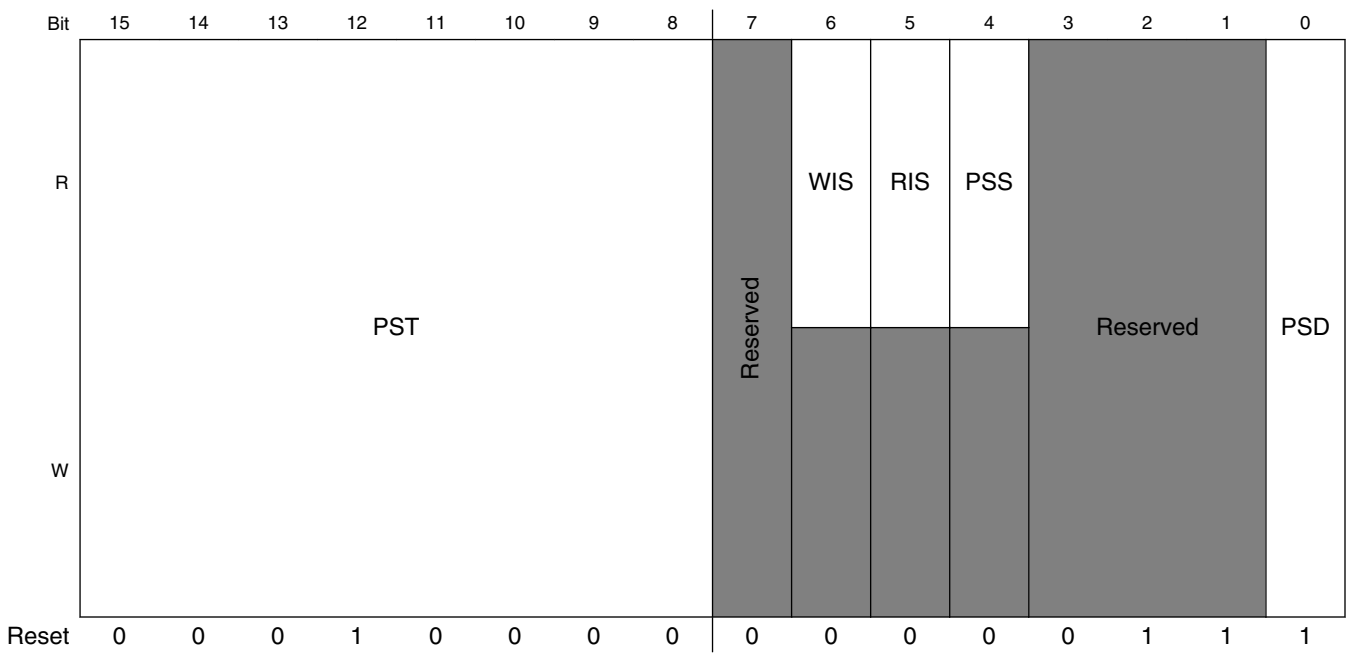
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 404h offset





MMDCx_MAPSR field descriptions

Field	Description
31–26 Reserved	This field is reserved. Reserved
25 DVACK	General DVFS acknowledge. This read only bit indicates whether a dvfs acknowledge was asserted and that MMDC is in self-refresh mode
24 LPACK	General low-power acknowledge. This read only bit indicates whether a low-power acknowledge was asserted and that MMDC is in self-refresh mode
23–22 Reserved	This field is reserved. Reserved
21 DVFS	General DVFS request. SW request for DVFS. Assertion of this bit will yield in self-refresh entry sequence 0 no dvfs request 1 dvfs request
20 LPMD	General LPMD request. SW request for LPMD. Assertion of this bit will yield in self-refresh entry sequence 0 no lpmd request 1 lpmd request
19–16 Reserved	This field is reserved. Reserved
15–8 PST	Automatic Power saving timer. Valid only when PSD is set to "0". When the MMDC is idle for amount of cycles specified in that field then the DDR device will be entered automatically into self-refresh mode. The real value which is used is register-value multiplied by 64. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 64 clock cycles. 00000010 timer is configured to 128 clock cycles. 00010000 (Default)- 1024 clock cycles. 11111111 timer clock is configured to 16320 clock cycles.
7 Reserved	This field is reserved. Reserved.
6 WIS	Write Idle Status. This read only bit indicates whether write request buffer is idle (empty) or not. 0 idle 1 not idle
5 RIS	Read Idle Status. This read only bit indicates whether read request buffer is idle (empty) or not. 0 idle 1 not idle
4 PSS	Power Saving Status. This read only bit indicates whether the MMDC is in automatic power saving mode. 0 not in power saving 1 power saving
3–1 Reserved	This field is reserved. Reserved.
0 PSD	Automatic Power Saving Disable. When the value of PSD is "0" (i.e automatic power saving is enabled) then the PST is activated and MMDC will enter automatically to self-refresh while the number of idle cycle reached.

Table continues on the next page...

MMDCx_MAPSR field descriptions (continued)

Field	Description
	NOTE: This bit must be disabled (i.e set to "1") during calibration process 0 power saving enabled 1 power saving disabled (default)

44.12.18 MMDC Core Exclusive ID Monitor Register0 (MMDCx_MAEXIDR0)

This register defines the ID to be monitored for exclusive accesses of monitor0 and monitor1. For further information see Exclusive accesses handling .

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 408h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MMDCx_MAEXIDR0 field descriptions

Field	Description
31–16 EXC_ID_ MONITOR1	This field defines ID for Exclusive monitor#1. Default value is 0x0020
EXC_ID_ MONITOR0	This field defines ID for Exclusive monitor#0. Default value is 0x0000

44.12.19 MMDC Core Exclusive ID Monitor Register1 (MMDCx_MAEXIDR1)

This register defines the ID to be monitored for exclusive accesses of monitor2 and monitor3. For further information see Exclusive accesses handling .

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 40Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	0						SBS	SBS_EN	0				CYC_OVF	PRF_FRZ	DBG_RST	DBG_EN
W													w1c			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MMDCx_MADPCR0 field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 SBS	Step By Step trigger. If SBS_EN is set to "1" then dispatching AXI pending access toward the DDR will done only if this bit is set to "1", otherwise no access will be dispatched toward the DDR. This bit is cleared when the pending access has been issued toward the DDR device. 1 Launch AXI pending access toward the DDR 0 No access will be launched toward the DDR
8 SBS_EN	Step By Step debug Enable. Enable step by step mode. Every time this mechanism is enabled then setting SBS to "1" will dispatch one pending AXI access to the DDR and in parallel its attributes will be observed in the status registes (MASBS0 and MASBS1). For further information see Step By Step (SBS) software monitor . 0 disable 1 enable
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 CYC_OVF	Total Profiling Cycles Count Overflow. When profiling mechanism is enabled (DBG_EN is set to "1") then this bit is asserted when overflow of CYC_COUNT occurred. Cleared by writing 1 to it. 0 no overflow 1 overflow
2 PRF_FRZ	Profiling freeze. When this bit is asserted then the profiling mechanism will be froze and the associated status registers (MADPSR0-MADPSR5) will hold the the current profiling values. 0 profiling counters are not frozen 1 profiling counters are frozen
1 DBG_RST	Debug and Profiling Reset. Reset all debug and profiling counters and components. 0 no reset 1 reset
0 DBG_EN	Debug and Profiling Enable. Enable debug and profiling mechanism. When this bit is asserted then the MMDC will perform a profiling based on the ID that is configured to MADPCR1. Upon assertion of PRF_FRZ the profiling will be froze and the profiling results will be sampled to the status registers (MADPSR0-MADPSR5). For further information see MMDC Profiling . default is "disable" 0 disable 1 enable

44.12.21 MMDC Core Debug and Profiling Control Register 1 (MMDCx_MADPCR1)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 414h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PRF_AXI_ID_MASK																PRF_AXI_ID															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MMDCx_MADPCR1 field descriptions

Field	Description
31–16 PRF_AXI_ID_ MASK	Profiling AXI ID Mask. AXI ID bits which masked by this value are chosen for profiling. 1 AXI ID specific bit is chosen for profiling 0 AXI ID specific bit is ignored (don't care)
PRF_AXI_ID	Profiling AXI ID. AXI IDs that matches a bit-wise AND logic operation between PRF_AXI_ID and PRF_AXI_ID_MASK are chosen for profiling. Default value is 0x0, to choose any ID-s for profiling

44.12.22 MMDC Core Debug and Profiling Status Register 0 (MMDCx_MADPSR0)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 418h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MMDCx_MADPSR0 field descriptions

Field	Description
CYC_COUNT	Total Profiling cycle Count. This field reflects the total cycle count in case the profiling mechanism is enabled from assertion of DBG_EN and until PRF_FRZ is asserted

44.12.23 MMDC Core Debug and Profiling Status Register 1 (MMDCx_MADPSR1)

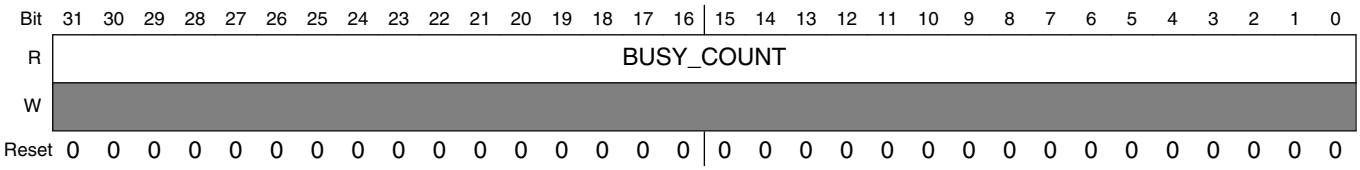
The register reflects the total cycles during which the MMDC state machines were busy (both writes and reads). This information can be used for DDR Utilization calculation.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 41Ch offset



MMDCx_MADPSR1 field descriptions

Field	Description
BUSY_COUNT	Profiling Busy Cycles Count. This field reflects the total number of cycles where the MMDC read and write state machines were busy during the profiling period. Can be used for DDR utilization calculations. Busy cycles are any MMDC clock cycles where the internal state machine is not idle. If any read or write requests are pending in the FIFOs, the MMDC is not idle.

44.12.24 MMDC Core Debug and Profiling Status Register 2 (MMDCx_MADPSR2)

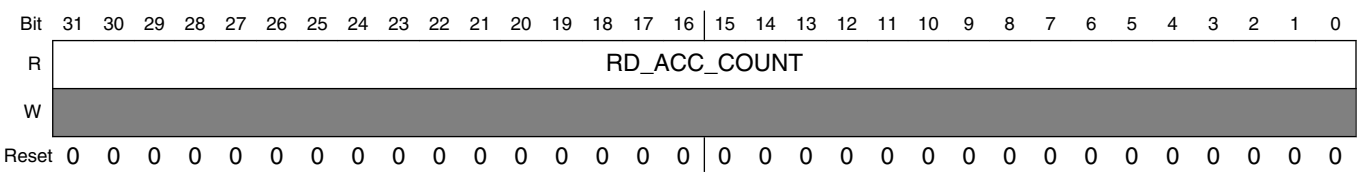
This register reflects the total number of read accesses (per AXI ID) toward MMDC.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 420h offset



MMDCx_MADPSR2 field descriptions

Field	Description
RD_ACC_ COUNT	Profiling Read Access Count. This register reflects the total number of read accesses (per AXI ID) toward MMDC.

44.12.25 MMDC Core Debug and Profiling Status Register 3 (MMDCx_MADPSR3)

This register reflects the total number of write accesses (per AXI ID) toward MMDC.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 424h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WR_ACC_COUNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MMDCx_MADPSR3 field descriptions

Field	Description
WR_ACC_COUNT	Profiling Write Access Count. This register reflects the total number of write accesses (per AXI ID) toward MMDC.

44.12.26 MMDC Core Debug and Profiling Status Register 4 (MMDCx_MADPSR4)

This register reflects the total number of bytes that were transferred during read access (per AXI ID) toward MMDC.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 428h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MMDCx_MADPSR4 field descriptions

Field	Description
RD_BYTES_COUNT	Profiling Read Bytes Count. This register reflects the total number of bytes that were transferred during read access (per AXI ID) toward MMDC.

44.12.27 MMDC Core Debug and Profiling Status Register 5 (MMDCx_MADPSR5)

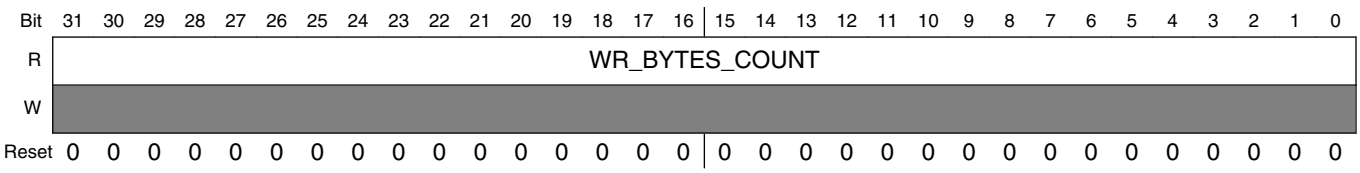
This register reflects the total number of bytes that were transferred during write access (per AXI ID) toward MMDC.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 42Ch offset



MMDCx_MADPSR5 field descriptions

Field	Description
WR_BYTES_COUNT	Profiling Write Bytes Count. This register reflects the total number of bytes that were transferred during write access (per AXI ID) toward MMDC.

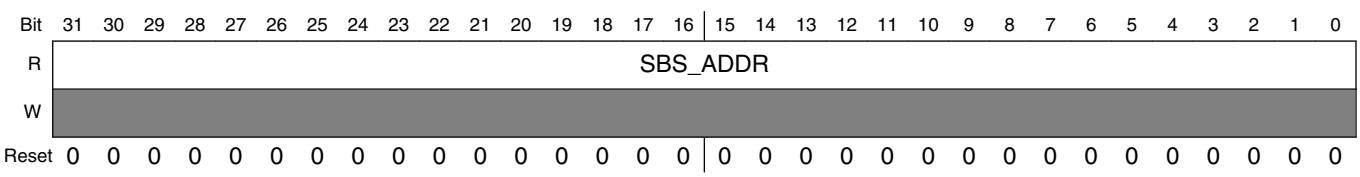
44.12.28 MMDC Core Step By Step Address Register (MMDCx_MASBS0)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 430h offset



MMDCx_MASBS0 field descriptions

Field	Description
SBS_ADDR	Step By Step Address. These bits reflect the address of the pending request in case of step by step mode.

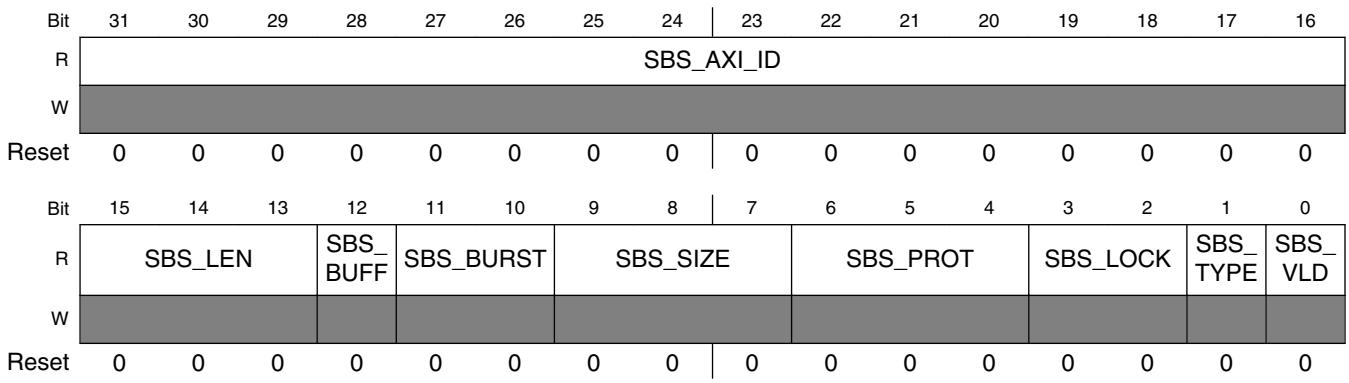
44.12.29 MMDC Core Step By Step Address Attributes Register (MMDCx_MASBS1)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 434h offset



MMDCx_MASBS1 field descriptions

Field	Description
31–16 SBS_AXI_ID	Step By Step AXI ID. These bits reflect the AXI ID of the pending request in case of step by step mode.
15–13 SBS_LEN	Step By Step Length. These bits reflect the AXI LENGTH of the pending request in case of step by step mode. 000 burst of length 1 001 burst of length 2 111 burst of length 8
12 SBS_BUFF	Step By Step Buffered. This bit reflect the AXI CACHE[0] of the pending request in case of step by step mode. Relevant only for write requests
11–10 SBS_BURST	Step By Step Burst. These bits reflect the AXI BURST of the pending request in case of step by step mode. 00 FIXED 01 INCR burst 10 WRAP burst 11 reserved
9–7 SBS_SIZE	Step By Step Size. These bits reflect the AXI SIZE of the pending request in case of step by step mode. 000 8 bits 001 16 bits 010 32 bits 011 64 bits

Table continues on the next page...

MMDCx_MASBS1 field descriptions (continued)

Field	Description
	100 128bits 101-111 Reserved
6–4 SBS_PROT	Step By Step Protection. These bits reflect the AXI PROT of the pending request in case of step by step mode.
3–2 SBS_LOCK	Step By Step Lock. These bits reflect the AXI LOCK of the pending request in case of step by step mode.
1 SBS_TYPE	Step By Step Request Type. These bits reflect the type (read/write) of the pending request in case of step by step mode. 0 write 1 read
0 SBS_VLD	Step By Step Valid. This bit reflects whether there is a pending request in case of step by step mode. 0 not valid 1 valid

44.12.30 MMDC Core General Purpose Register (MMDCx_MAGENP)

This register is a general 32 bit read/write register.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 440h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MMDCx_MAGENP field descriptions

Field	Description
GP31_GP0	General purpose read/write bits.

44.12.31 MMDC PHY ZQ HW control register (MMDCx_MPZQHWCTRL)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: This register is reserved for channel 1. Channel 1 ZQ is also controlled by MMDC0_MPZQHWCTRL.

Address: Base address + 800h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MMDCx_MPZQHWCTRL field descriptions

Field	Description
31–27 ZQ_EARLY_COMPARATOR_EN_TIMER	ZQ early comparator enable timer. This timer defines the interval between the warming up of the comparator of the i.MX ZQ calibration pad and the beginning of the ZQ calibration process with the pad 0x0 - 0x6 Reserved 0x7 8 cycles 0x14 21 cycles (Default) 0x1E 31 cycles 0x1F 32 cycles
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–23 TZQ_CS	Device ZQ short time. This field holds the number of cycles that are required by the external DDR device to perform ZQ short calibration. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. **NOTE:** In LPDDR2 the ZQ short time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQCS] **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles (Default) 011 256 cycles 100 512 cycles 101 1024 cycles 110- 111 Reserved
22–20 TZQ_OPER	Device ZQ long/oper time. This field holds the number of cycles that are required by the external DDR device to perform ZQ long calibration except the first ZQ long command that is issued after reset. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. **NOTE:** In LPDDR2 the ZQ oper time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQCL] **NOTE:** This field should not be update during ZQ calibration. 000 Reserved

Table continues on the next page...

MMDCx_MPZQHWCTRL field descriptions (continued)

Field	Description
	001 Reserved 010 128 cycles 011 256 cycles - Default (JEDEC value for DDR3) 100 512 cycles 101 1024 cycles 110- 111 Reserved
19–17 TZQ_INIT	Device ZQ long/init time. This field holds the number of cycles that are required by the external DDR device to perform ZQ long calibration right after reset. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. **NOTE:** In LPDDR2 the ZQ init time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQINIT] **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles 011 256 cycles 100 512 cycles - Default (JEDEC value for DDR3) 101 1024 cycles 110- 111 Reserved
16 ZQ_HW_FOR	Force ZQ automatic calibration process with the i.MX ZQ calibration pad. When this bit is asserted then the MMDC will issue one ZQ automatic calibration process with the i.MX ZQ calibration pad. It is the user responsibility to make sure that all the accesses to DDR will be finished before asserting this bit using CON_REQ/CON_ACK mechanism. HW will negate this bit upon completion of the ZQ calibration process. Upon negation of this bit the ZQ HW calibration pull-up and pull-down results (ZQ_HW_PU_RES and ZQ_HW_PD_RES respectively) are valid **NOTE:** In order to enable this bit ZQ_MODE must be set to either "1" or "3"
15–11 ZQ_HW_PD_ RES	ZQ HW calibration pull-down result. This field holds the pull-down resistor value calculated at the end of the ZQ automatic calibration process with the i.MX ZQ calibration pad. **NOTE:** An offset can be applied to this result, see MMDC_MPPDCMPR2[ZQ_PD_OFFSET]. 00000 Max. resistance. 11111 Min. resistance.
10–6 ZQ_HW_PU_ RES	ZQ automatic calibration pull-up result. This field holds the pull-up resistor value calculated at the end of the ZQ automatic calibration process with the i.MX ZQ calibration pad. **NOTE:** An offset can be applied to this result, see MMDC_MPPDCMPR2[ZQ_PU_OFFSET] 00000 Min. resistance. 11111 Max. resistance.
5–2 ZQ_HW_PER	ZQ periodic calibration time. This field determines how often the periodic ZQ calibration is performed. This field is applied for both ZQ short calibration and ZQ automatic calibration process with i.MX ZQ calibration pad. Whenever this timer is expired then according to ZQ_MODE the ZQ automatic calibration process with the i.MX ZQ calibration pad will be issued and/or short/long command will be issued to the external DDR device. This field is ignored if ZQ_MODE equals "00" 0000 ZQ calibration is performed every 1 ms.

Table continues on the next page...

MMDCx_MPZQHWCTRL field descriptions (continued)

Field	Description
	0001 ZQ calibration is performed every 2 ms. 0010 ZQ calibration is performed every 4 ms. 1010 ZQ calibration is performed every 1 sec. 1110 ZQ calibration is performed every 16 sec. 1111 ZQ calibration is performed every 32 sec.
ZQ_MODE	ZQ calibration mode: 0x0 No ZQ calibration is issued. (Default) 0x1 ZQ calibration is issued to i.MX ZQ calibration pad together with ZQ long command to the external DDR device only when exiting self refresh. 0x2 ZQ calibration command long/short is issued only to the external DDR device periodically and when exiting self refresh 0x3 ZQ calibration is issued to i.MX ZQ calibration pad together with ZQ calibration command long/ short to the external DDR device periodically and when exiting self refresh

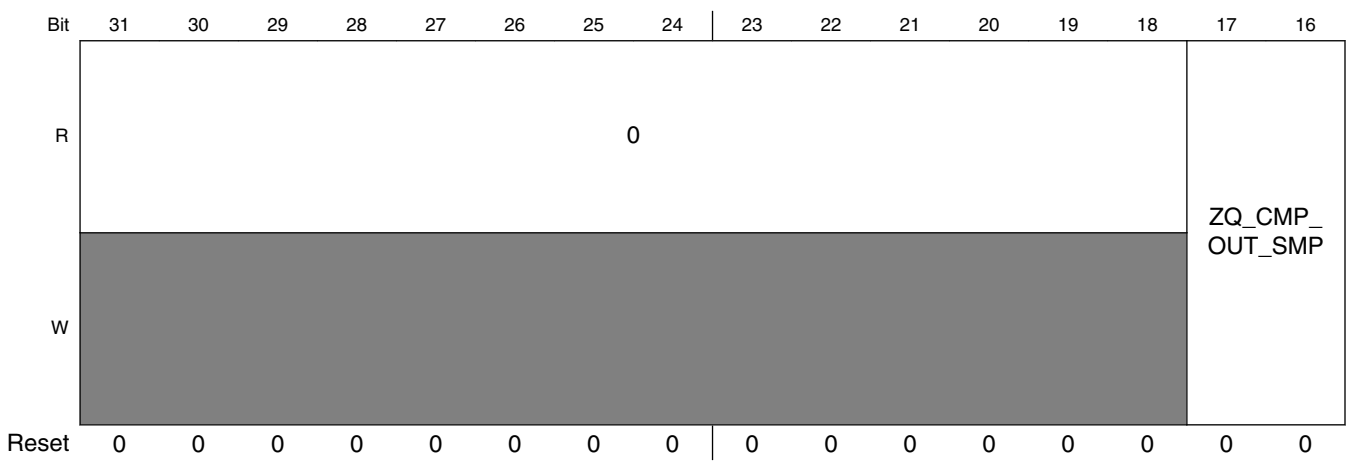
44.12.32 MMDC PHY ZQ SW control register (MMDCx_MPZQSWCTRL)

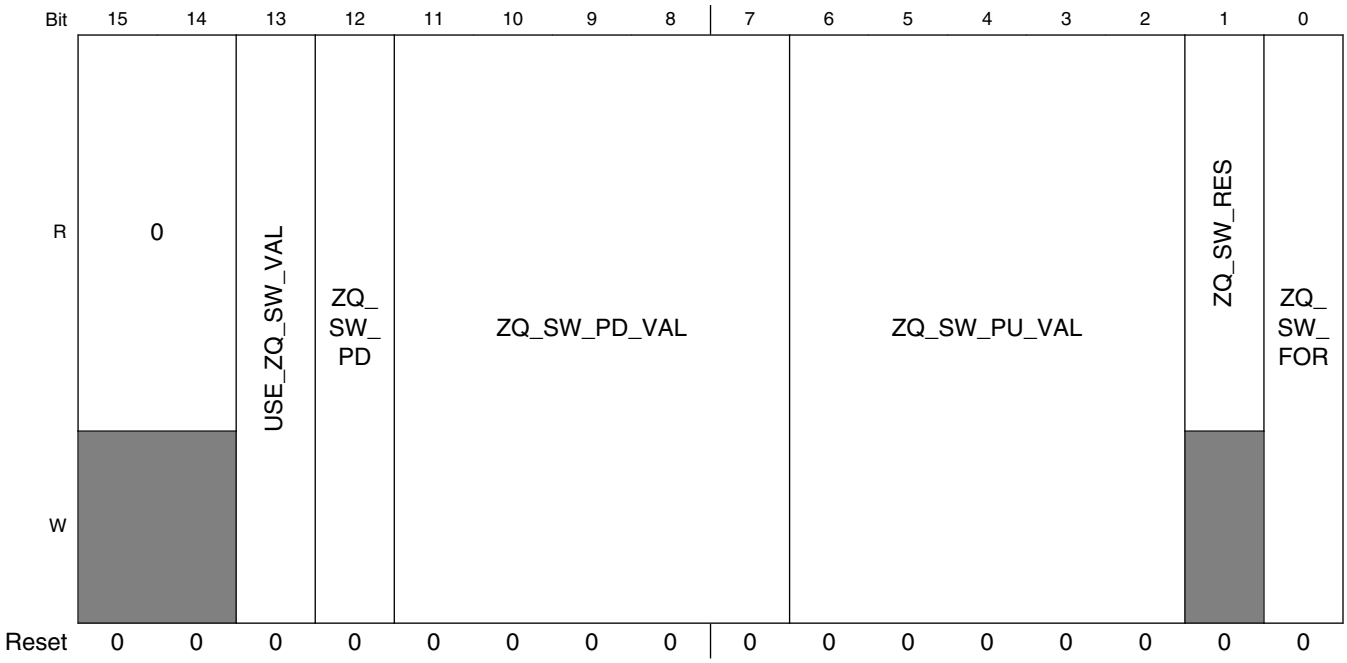
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: This register is reserved. Channel 1 ZQ is also controlled by MMDC0_MPZQHWCTRL.

Address: Base address + 804h offset





MMDCx_MPZQSWCTRL field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 ZQ_CMP_OUT_SMP	Defines the amount of cycles between driving the ZQ signals to the ZQ pad and till sampling the comparator enable output while performing ZQ calibration process with the i.MX ZQ calibration pad 00 7 cycles 01 15 cycles 10 23 cycles 11 31 cycles
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 USE_ZQ_SW_VAL	Use SW ZQ configured value for I/O pads resistor controls. This bit selects whether ZQ SW value or ZQ HW value will be driven to the I/O pads resistor controls. By default this bit is cleared and MMDC drives the HW ZQ status bits on the resistor controls of the I/O pads. **NOTE:** This bit should not be updated during ZQ calibration. 0 Fields ZQ_HW_PD_VAL & ZQ_HW_PU_VAL will be driven to I/O pads resistor controls. 1 Fields ZQ_SW_PD_VAL & ZQ_SW_PU_VAL will be driven to I/O pads resistor controls.
12 ZQ_SW_PD	ZQ software PU/PD calibration. This bit determines the calibration stage (PU or PD). 0 PU resistor calibration 1 PD resistor calibration
11–7 ZQ_SW_PD_VAL	ZQ software pull-down resistence. This field determines the value of the PD resistor during SW ZQ calibration. 00000 Max. resistance. 11111 Min. resistance.

Table continues on the next page...

MMDCx_MPZQSWCTRL field descriptions (continued)

Field	Description
6–2 ZQ_SW_PU_VAL	ZQ software pull-up resistence. This field determines the value of the PU resistor during SW ZQ calibration. 00000 Min. resistance. 11111 Max. resistance.
1 ZQ_SW_RES	ZQ software calibration result. This bit reflects the ZQ calibration voltage comparator value. 0 Current ZQ calibration voltage is less than VDD/2. 1 Current ZQ calibration voltage is more than VDD/2
0 ZQ_SW_FOR	ZQ SW calibration enable. This bit when asserted enables ZQ SW calibration. HW negates this bit upon completion of the ZQ SW calibration. Upon negation of this bit the ZQ SW calibration result (i.e ZQ_SW_RES) is valid

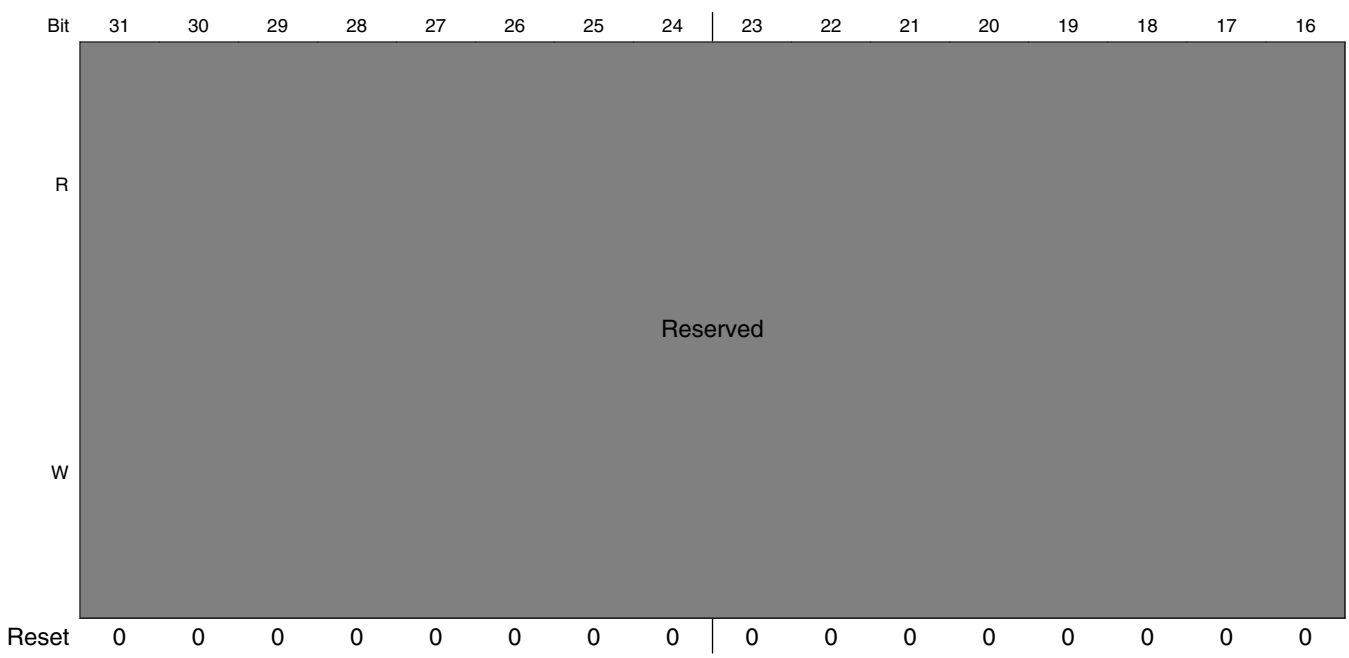
44.12.33 MMDC PHY Write Leveling Configuration and Error Status Register (MMDCx_MPWLGCR)

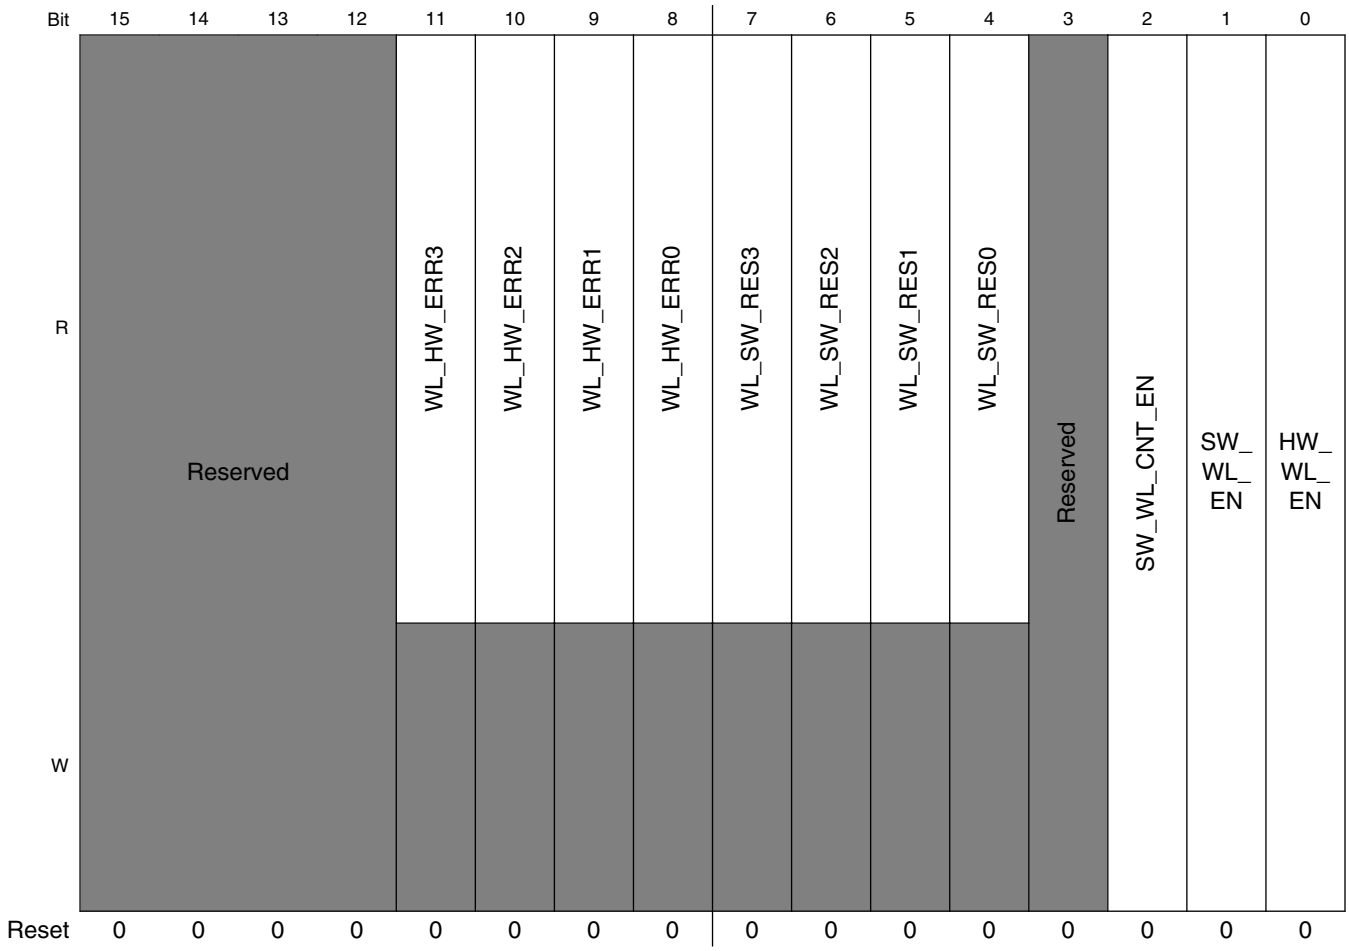
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 808h offset





MMDCx_MPWLGCR field descriptions

Field	Description
31–12 Reserved	This field is reserved. Reserved
11 WL_HW_ERR3	Byte3 write-leveling HW calibration error. This bit is asserted when an error was found on byte3 during write-leveling HW calibration. This bit is valid only upon completion of the write-leveling HW calibration (i.e. HW_WL_EN bit is de-asserted) 0 No error was found on byte3 during write-leveling HW calibration. 1 An error was found on byte3 during write-leveling HW calibration.
10 WL_HW_ERR2	Byte2 write-leveling HW calibration error. This bit is asserted when an error was found on byte2 during write-leveling HW calibration. This bit is valid only upon completion of the write-leveling HW calibration (i.e. HW_WL_EN bit is de-asserted) 0 No error was found on byte2 during write-leveling HW calibration. 1 An error was found on byte2 during write-leveling HW calibration.
9 WL_HW_ERR1	Byte1 write-leveling HW calibration error. This bit is asserted when an error was found on byte1 during write-leveling HW calibration.

Table continues on the next page...

MMDCx_MPWLGCR field descriptions (continued)

Field	Description
	This bit is valid only upon completion of the write-leveling HW calibration (i.e. HW_WL_EN bit is de-asserted) 0 No error was found on byte1 during write-leveling HW calibration. 1 An error was found on byte1 during write-leveling HW calibration.
8 WL_HW_ERR0	Byte0 write-leveling HW calibration error. This bit is asserted when an error was found on byte0 during write-leveling HW calibration. This bit is valid only upon completion of the write-leveling HW calibration (i.e. HW_WL_EN bit is de-asserted) 0 No error was found on byte0 during write-leveling HW calibration. 1 An error was found on byte0 during write-leveling HW calibration.
7 WL_SW_RES3	Byte3 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ24 during SW write-leveling. 0 DQS3 sampled low CK during SW write-leveling. 1 DQS3 sampled high CK during SW write-leveling.
6 WL_SW_RES2	Byte2 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ16 during SW write-leveling. 0 DQS2 sampled low CK during SW write-leveling. 1 DQS2 sampled high CK during SW write-leveling.
5 WL_SW_RES1	Byte1 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ8 during SW write-leveling. 0 DQS1 sampled low CK during SW write-leveling. 1 DQS1 sampled high CK during SW write-leveling.
4 WL_SW_RES0	Byte0 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ0 during SW write-leveling. 0 DQS0 sampled low CK during SW write-leveling. 1 DQS0 sampled high CK during SW write-leveling.
3 Reserved	This field is reserved. Reserved
2 SW_WL_CNT_EN	SW write-leveling count down enable. This bit when asserted set a certain delay of (25+15) cycles from the setting of SW_WL_EN and before driving the DQS to the DDR device. This bit should be asserted before the first SW write-leveling request and after issuing the write leveling MRS command 0 MMDC doesn't count 25+15 cycles before issuing write-leveling DQS. 1 MMDC counts 25+15 cycles before issuing write-leveling DQS.
1 SW_WL_EN	Write-Leveling SW enable. If this bit is asserted then the MMDC will perform one write-leveling iteration with the DDR device (assuming that Write-Leveling procedure is already enabled in the DDR device through MRS command). HW negate this bit upon completion of the SW write-leveling. Negation of this bit also points that the write-leveling SW calibration result is valid **NOTE:** If this bit and the SW_WL_CNT_EN are enabled the MMDC counts 25 + 15 cycles before issuing the SW write-leveling DQS.
0 HW_WL_EN	Write-Leveling HW (automatic) enable. If this bit is asserted then the MMDC will perform the whole Write-Leveling sequence with the DDR device (assuming that Write-Leveling procedure is already enabled in the DDR device through MRS command). HW negates this bit upon completion of the HW write-leveling. Negation of this bit also points that the write-leveling HW calibration results are valid

Table continues on the next page...

MMDCx_MPWLGCR field descriptions (continued)

Field	Description
	NOTE: Before issuing the first DQS the MMDC counts 25 + 15 cycles automatically as required by the standard.

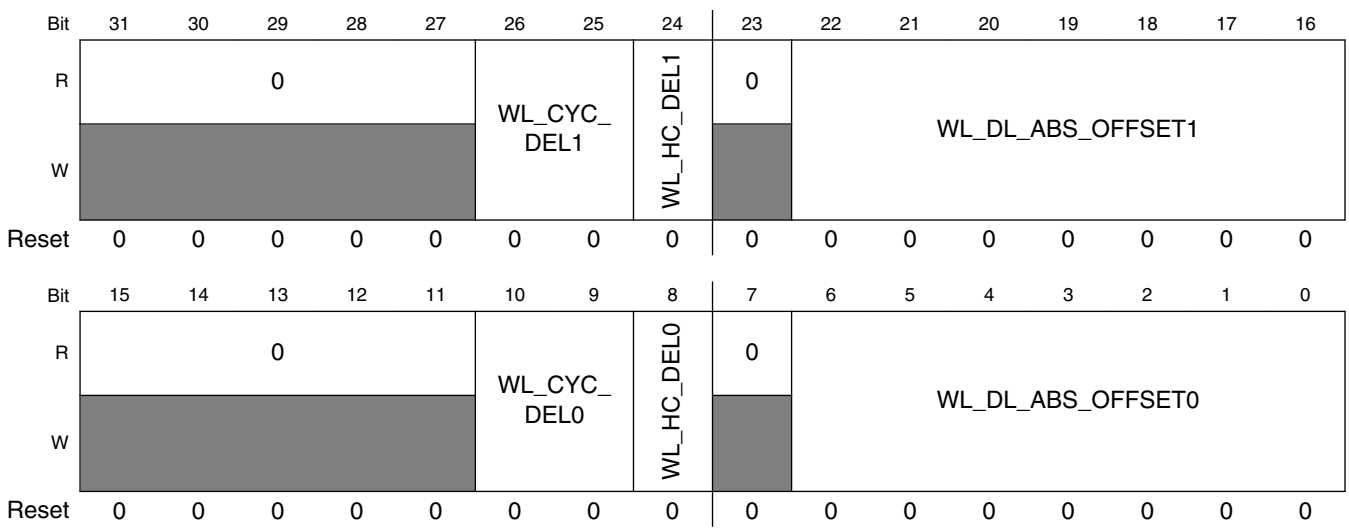
44.12.34 MMDC PHY Write Leveling Delay Control Register 0 (MMDCx_MPWLDECTRL0)

Supported Mode OF Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 80Ch offset



MMDCx_MPWLDECTRL0 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–25 WL_CYC_DEL1	Write leveling cycle delay for Byte 1. This field indicates whether a delay of 1 or 2 cycles between CK and write DQS is added to the delay that is indicated in the associated WR_DL_ABS_OFFSET and WL_HC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle). When both SW write-leveling is enabled (i.e. SW_WL_EN = 1) or HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_HC_DEL. Note that in HW write-leveling this field is not used for indication, as in WL_DL_OFFSET and WL_HC_DEL, but for configuration. 0 No delay is added.

Table continues on the next page...

MMDCx_MPWLDECTRL0 field descriptions (continued)

Field	Description
	1 1 cycle delay is added. 2 2 cycles delay is added. 3 Reserved.
24 WL_HC_DEL1	Write leveling half cycle delay for Byte 1. This field indicates whether a delay of half cycle between CK and write DQS is added to the delay that is indicated in the associated WR_DL_ABS_OFFSET and WL_CYC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle). When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_CYC_DEL. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) whether a delay of half cycle was added or not to the associated WL_DL_OFFSET and WL_CYC_DEL. 0 No delay is added. 1 Half cycle delay is added.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 WL_DL_ABS_OFFSET1	Absolute write-leveling delay offset for Byte 1. This field indicates the absolute delay between CK and write DQS of Byte1 with fractions of a clock period and up to half cycle. This value is process and frequency independent. The value of the delay can be calculated using the following equation (WR_DL_ABS_OFFSET1 / 256) * clock period When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is to the associated delay-line. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) the value that is taken to the associated delay-line at the end of the write-leveling calibration. **NOTE:** The delay-line has a resolution that may vary between device to device, therefore is some cases an increment of the delay by 1 step may be smaller than the delay-line resolution.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–9 WL_CYC_DEL0	Write leveling cycle delay for Byte 0. This field indicates whether a delay of 1 or 2 cycles between CK and write DQS is added to the delay that is indicated in the associated WR_DL_ABS_OFFSET and WL_HC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle). When both SW write-leveling is enabled (i.e. SW_WL_EN = 1) or HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_HC_DEL. Note that in HW write-leveling this field is not used for indication, as in WL_DL_OFFSET and WL_HC_DEL, but for configuration. 0 No delay is added. 1 1 cycle delay is added. 2 2 cycles delay is added. 3 Reserved.
8 WL_HC_DEL0	Write leveling half cycle delay for Byte 0. This field indicates whether a delay of half cycle between CK and write DQS is added to the delay that is indicated in the associated WR_DL_ABS_OFFSET and WL_CYC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle).

Table continues on the next page...

MMDCx_MPWLDECTRL0 field descriptions (continued)

Field	Description
	When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_CYC_DEL. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) whether a delay of half cycle was added or not to the associated WL_DL_OFFSET and WL_CYC_DEL. 0 No delay is added. 1 Half cycle delay is added.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
WL_DL_ABS_OFFSET0	Absolute write-leveling delay offset for Byte 0. This field indicates the absolute delay between CK and write DQS of Byte0 with fractions of a clock period and up to half cycle. This value is process and frequency independent. The value of the delay can be calculated using the following equation (WR_DL_ABS_OFFSET1 / 256) * clock period When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is to the associated delay-line. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) the value that is taken to the associated delay-line at the end of the write-leveling calibration. **NOTE:** The delay-line has a resolution that may vary between device to device, therefore is some cases an increment of the delay by 1 step may be smaller than the delay-line resolution.

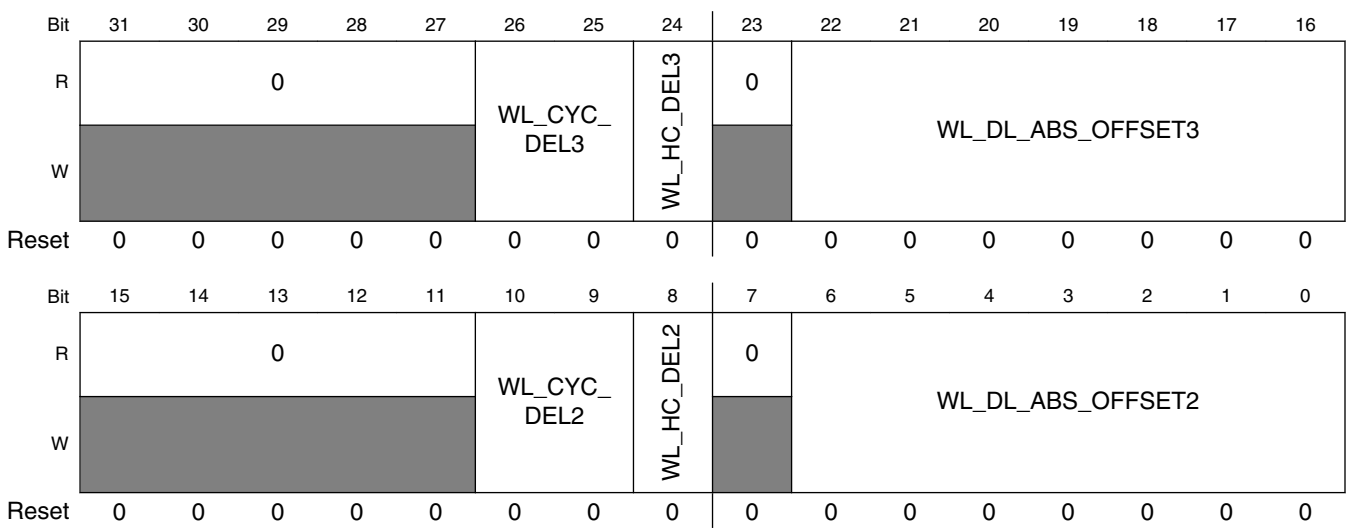
44.12.35 MMDC PHY Write Leveling Delay Control Register 1 (MMDCx_MPWLDECTRL1)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x32

Address: Base address + 810h offset



MMDCx_MPWLDECTRL1 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–25 WL_CYC_DEL3	Write leveling cycle delay for Byte 3. This field indicates whether a delay of 1 or 2 cycles between CK and write DQS is added to the delay that is indicated in the associated WL_DL_ABS_OFFSET and WL_HC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle). When both SW write-leveling is enabled (i.e. SW_WL_EN = 1) or HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_HC_DEL. Note that in HW write-leveling this field is not used for indication, as in WL_DL_OFFSET and WL_HC_DEL, but for configuration. 0 No delay is added. 1 1 cycle delay is added. 2 2 cycles delay is added. 3 Reserved.
24 WL_HC_DEL3	Write leveling half cycle delay for Byte 3. This field indicates whether a delay of half cycle between CK and write DQS is added to the delay that is indicated in the associated WL_DL_ABS_OFFSET and WL_CYC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle). When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_CYC_DEL. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) whether a delay of half cycle was added or not to the associated WL_DL_OFFSET and WL_CYC_DEL. 0 No delay is added. 1 Half cycle delay is added.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 WL_DL_ABS_ OFFSET3	Absolute write-leveling delay offset for Byte 3. This field indicates the absolute delay between CK and write DQS of Byte3 with fractions of a clock period and up to half cycle. This value is process and frequency independent. The value of the delay can be calculated using the following equation (WL_DL_ABS_OFFSET3 / 256) * clock period When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is to the associated delay-line. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) the value that is taken to the associated delay-line at the end of the write-leveling calibration. **NOTE:** The delay-line has a resolution that may vary between device to device, therefore is some cases an increment of the delay by 1 step may be smaller than the delay-line resolution.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–9 WL_CYC_DEL2	Write leveling cycle delay for Byte 2. This field indicates whether a delay of 1 or 2 cycles between CK and write DQS is added to the delay that is indicated in the associated WR_DL_ABS_OFFSET and WL_HC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle). When both SW write-leveling is enabled (i.e. SW_WL_EN = 1) or HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_HC_DEL.

MMDCx_MPWLDECTRL1 field descriptions (continued)

Field	Description
	Note that in HW write-leveling this field is not used for indication, as in WL_DL_OFFSET and WL_HC_DEL, but for configuration. 0 No delay is added. 1 1 cycle delay is added. 2 2 cycles delay is added. 3 Reserved.
8 WL_HC_DEL2	Write leveling half cycle delay for Byte 2. This field indicates whether a delay of half cycle between CK and write DQS is added to the delay that is indicated in the associated WR_DL_ABS_OFFSET and WL_CYC_DEL. So the total delay is the sum of (WL_DL_ABS_OFFSET/256*cycle) + (WL_HC_DEL*half cycle) + (WL_CYC_DEL*cycle). When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is and will be added to the associated delay that is configured in WL_DL_OFFSET and WL_CYC_DEL. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) whether a delay of half cycle was added or not to the associated WL_DL_OFFSET and WL_CYC_DEL. 0 No delay is added. 1 Half cycle delay is added.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
WL_DL_ABS_ OFFSET2	Absolute write-leveling delay offset for Byte 2. This field indicates the absolute delay between CK and write DQS of Byte1 with fractions of a clock period and up to half cycle. This value is process and frequency independent. The value of the delay can be calculated using the following equation (WR_DL_ABS_OFFSET2 / 256) * clock period When SW write-leveling is enabled (i.e. SW_WL_EN = 1) then this value will be taken as is to the associated delay-line. When HW write-leveling is enabled (i.e. HW_WL_EN = 1) then this value will indicate (status) the value that is taken to the associated delay-line at the end of the write-leveling calibration. **NOTE:** The delay-line has a resolution that may vary between device to device, therefore is some cases an increment of the delay by 1 step may be smaller than the delay-line resolution.

44.12.36 MMDC PHY Write Leveling delay-line Status Register (MMDCx_MPWLDLST)

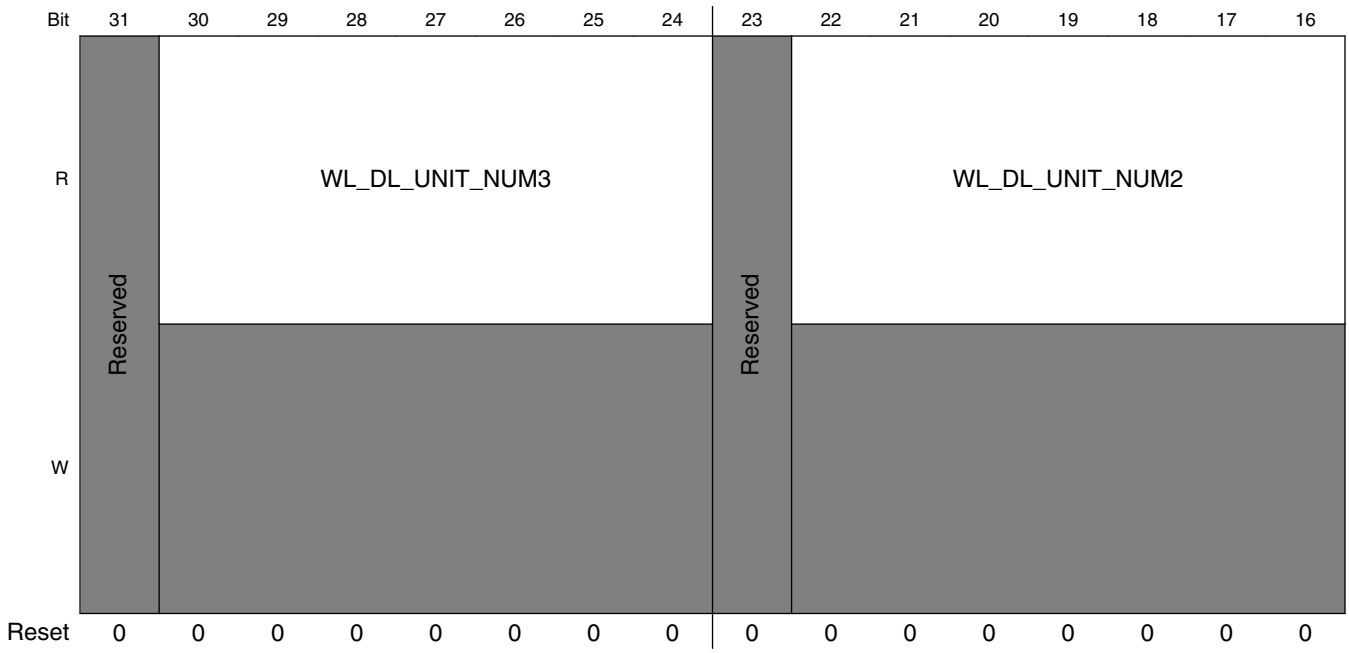
This register holds the status of the four write leveling delay-lines.

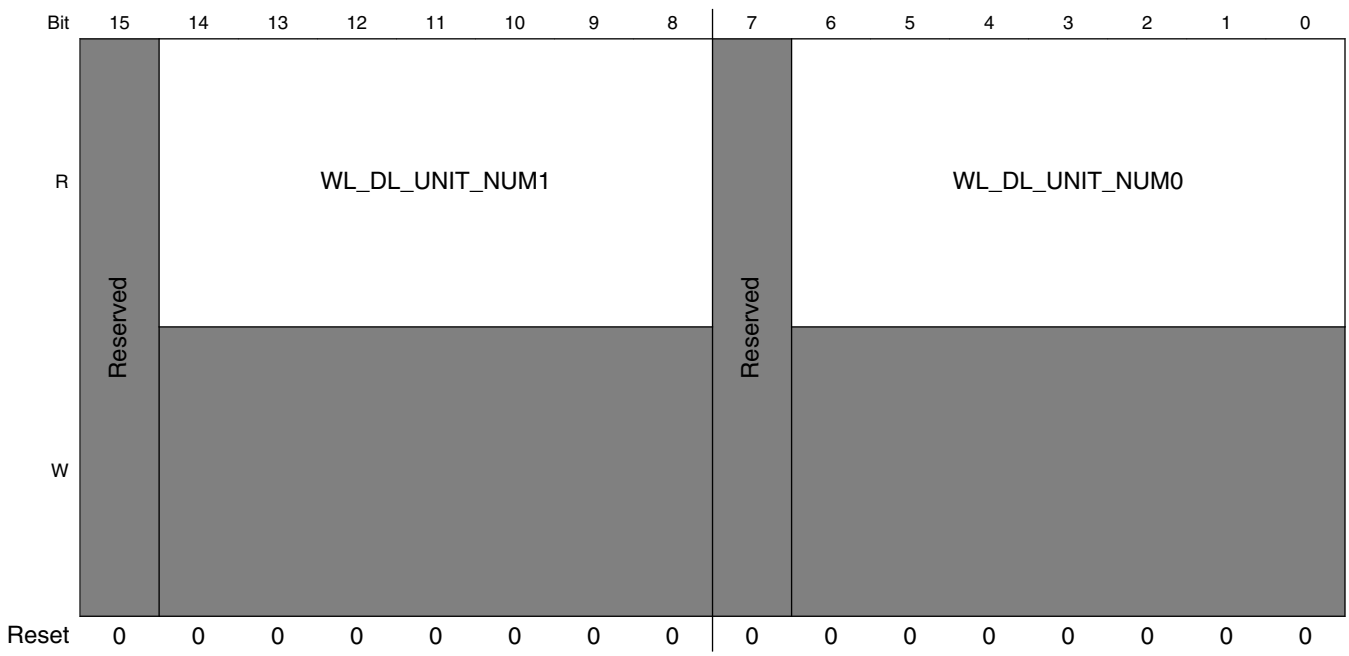
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 814h offset





MMDCx_MPWLDLST field descriptions

Field	Description
31 Reserved	This field is reserved. Reserved
30–24 WL_DL_UNIT_NUM3	This field reflects the number of delay units that are actually used by write leveling delay-line 3.
23 Reserved	This field is reserved. Reserved

Table continues on the next page...

MMDCx_MPWLDLST field descriptions (continued)

Field	Description
22–16 WL_DL_UNIT_NUM2	This field reflects the number of delay units that are actually used by write leveling delay-line 2.
15 Reserved	This field is reserved. Reserved
14–8 WL_DL_UNIT_NUM1	This field reflects the number of delay units that are actually used by write leveling delay-line 1.
7 Reserved	This field is reserved. Reserved
WL_DL_UNIT_NUM0	This field reflects the number of delay units that are actually used by write leveling delay-line 0.

44.12.37 MMDC PHY ODT control register (MMDCx_MPODTCTRL)

NOTE

In LPDDR2 mode this register should be cleared, so no termination will be activated

Supported Mode Of Operations:

For Channel 0: DDR3_x16, DDR3_x32, DDR3_x64

For Channel 1: DDR3_x64

Address: Base address + 818h offset

Field	Description
	100 Rtt_Nom 30 Ohm 101 Rtt_Nom 24 Ohm 110 Rtt_Nom 20 Ohm 111 Rtt_Nom 17 Ohm
3 ODT_RD_ACT_EN	Active read CS ODT enable. The bit determines if ODT pin of the active CS will be asserted during read accesses. 0 Active CS ODT pin is disabled during read access. 1 Active CS ODT pin is enabled during read access.
2 ODT_RD_PAS_EN	Inactive read CS ODT enable. The bit determines if ODT pin of the inactive CS will be asserted during read accesses. 0 Inactive CS ODT pin is disabled during read accesses to other CS. 1 Inactive CS ODT pin is enabled during read accesses to other CS.
1 ODT_WR_ACT_EN	Active write CS ODT enable. The bit determines if ODT pin of the active CS will be asserted during write accesses. 0 Active CS ODT pin is disabled during write access. 1 Active CS ODT pin is enabled during write access.
0 ODT_WR_PAS_EN	Inactive write CS ODT enable. The bit determines if ODT pin of the inactive CS will be asserted during write accesses. 0 Inactive CS ODT pin is disabled during write accesses to other CS. 1 Inactive CS ODT pin is enabled during write accesses to other CS.

44.12.38 MMDC PHY Read DQ Byte0 Delay Register (MMDCx_MPRDDQBY0DL)

This register is used to add fine-tuning adjustment to every bit in the read DQ byte0 relative to the read DQS. This delay is in addition to the read data calibration. If operating in 64-bit mode, there is an identical register that is mapped at the second base address.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 81Ch offset

This field holds the number of delay units that are added to dq17 relative to dqs2. 000 No change in dq17 delay 001 Add dq17 delay of 1 delay unit 010 Add dq17 delay of 2 delay units. 011 Add dq17 delay of 3 delay units. 100 Add dq17 delay of 4 delay units. 101 Add dq17 delay of 5 delay units. 110 Add dq17 delay of 6 delay units. 111 Add dq17 delay of 7 delay units.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
rd_dq16_del	Read dqs2 to dq16 delay fine-tuning. This field holds the number of delay units that are added to dq16 relative to dqs2. 000 No change in dq16 delay 001 Add dq16 delay of 1 delay unit 010 Add dq16 delay of 2 delay units. 011 Add dq16 delay of 3 delay units. 100 Add dq16 delay of 4 delay units. 101 Add dq16 delay of 5 delay units. 110 Add dq16 delay of 6 delay units. 111 Add dq16 delay of 7 delay units.

44.12.41 MMDC PHY Read DQ Byte3 Delay Register (MMDCx_MPRDDQBY3DL)

This register is used to add fine-tuning adjustment to every bit in the read DQ byte3 relative to the read DQS.

The bit assignments and the bit field descriptions for the register are shown below.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x32

Address: Base address + 828h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MMDCx_MPRDDQBY3DL field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–28 rd_dq31_del	Read dqs3 to dq31 delay fine-tuning. This field holds the number of delay units that are added to dq31 relative to dqs3. 000 No change in dq31 delay 001 Add dq31 delay of 1 delay unit 010 Add dq31 delay of 2 delay units. 011 Add dq31 delay of 3 delay units. 100 Add dq31 delay of 4 delay units. 101 Add dq31 delay of 5 delay units. 110 Add dq31 delay of 6 delay units. 111 Add dq31 delay of 7 delay units.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 rd_dq30_del	Read dqs3 to dq30 delay fine-tuning. This field holds the number of delay units that are added to dq30 relative to dqs3. 000 No change in dq30 delay 001 Add dq30 delay of 1 delay unit 010 Add dq30 delay of 2 delay units.

Table continues on the next page...

MMDCx_MPRDDQBY3DL field descriptions (continued)

Field	Description
	011 Add dq30 delay of 3 delay units. 100 Add dq30 delay of 4 delay units. 101 Add dq30 delay of 5 delay units. 110 Add dq30 delay of 6 delay units. 111 Add dq30 delay of 7 delay units.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–20 rd_dq29_del	Read dqs3 to dq29 delay fine-tuning. This field holds the number of delay units that are added to dq29 relative to dqs3. 000 No change in dq29 delay 001 Add dq29 delay of 1 delay unit 010 Add dq29 delay of 2 delay units. 011 Add dq29 delay of 3 delay units. 100 Add dq29 delay of 4 delay units. 101 Add dq29 delay of 5 delay units. 110 Add dq29 delay of 6 delay units. 111 Add dq29 delay of 7 delay units.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 rd_dq28_del	Read dqs3 to dq28 delay fine-tuning. This field holds the number of delay units that are added to dq28 relative to dqs3. 000 No change in dq28 delay 001 Add dq28 delay of 1 delay unit 010 Add dq28 delay of 2 delay units. 011 Add dq28 delay of 3 delay units. 100 Add dq28 delay of 4 delay units. 101 Add dq28 delay of 5 delay units. 110 Add dq28 delay of 6 delay units. 111 Add dq28 delay of 7 delay units.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–12 rd_dq27_del	Read dqs3 to dq27 delay fine-tuning. This field holds the number of delay units that are added to dq27 relative to dqs3. 000 No change in dq27 delay 001 Add dq27 delay of 1 delay unit 010 Add dq27 delay of 2 delay units. 011 Add dq27 delay of 3 delay units. 100 Add dq27 delay of 4 delay units. 101 Add dq27 delay of 5 delay units. 110 Add dq27 delay of 6 delay units. 111 Add dq27 delay of 7 delay units.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 rd_dq26_del	Read dqs3 to dq26 delay fine-tuning. This field holds the number of delay units that are added to dq26 relative to dqs3.

Table continues on the next page...

MMDCx_MPRDDQBY3DL field descriptions (continued)

Field	Description
	000 No change in dq26 delay 001 Add dq26 delay of 1 delay unit 010 Add dq26 delay of 2 delay units. 011 Add dq26 delay of 3 delay units. 100 Add dq26 delay of 4 delay units. 101 Add dq26 delay of 5 delay units. 110 Add dq26 delay of 6 delay units. 111 Add dq26 delay of 7 delay units.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 rd_dq25_del	Read dqs3 to dq25 delay fine-tuning. This field holds the number of delay units that are added to dq25 relative to dqs3. 000 No change in dq25 delay 001 Add dq25 delay of 1 delay unit 010 Add dq25 delay of 2 delay units. 011 Add dq25 delay of 3 delay units. 100 Add dq25 delay of 4 delay units. 101 Add dq25 delay of 5 delay units. 110 Add dq25 delay of 6 delay units. 111 Add dq25 delay of 7 delay units.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
rd_dq24_del	Read dqs3 to dq24 delay fine-tuning. This field holds the number of delay units that are added to dq24 relative to dqs3. 000 No change in dq24 delay 001 Add dq24 delay of 1 delay unit 010 Add dq24 delay of 2 delay units. 011 Add dq24 delay of 3 delay units. 100 Add dq24 delay of 4 delay units. 101 Add dq24 delay of 5 delay units. 110 Add dq24 delay of 6 delay units. 111 Add dq24 delay of 7 delay units.

44.12.42 MMDC PHY Write DQ Byte0 Delay Register (MMDCx_MPWRDQBY0DL)

This register is used to add fine-tuning adjustment to every bit in the write DQ byte0 relative to the write DQS

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 82Ch offset

5–4 wr_dq25_del	Write dq25 delay fine tuning. This field holds the number of delay units that are added to dq25 relative to dqs3. 00 No change in dq25 delay 01 Add dq25 delay of 1 delay unit. 10 Add dq25 delay of 2 delay units. 11 Add dq25 delay of 3 delay units.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
wr_dq24_del	Write dq24 delay fine tuning. This field holds the number of delay units that are added to dq24 relative to dqs3. 00 No change in dq24 delay 01 Add dq24 delay of 1 delay unit. 10 Add dq24 delay of 2 delay units. 11 Add dq24 delay of 3 delay units.

44.12.46 MMDC PHY Read DQS Gating Control Register 0 (MMDCx_MPDGCTRL0)

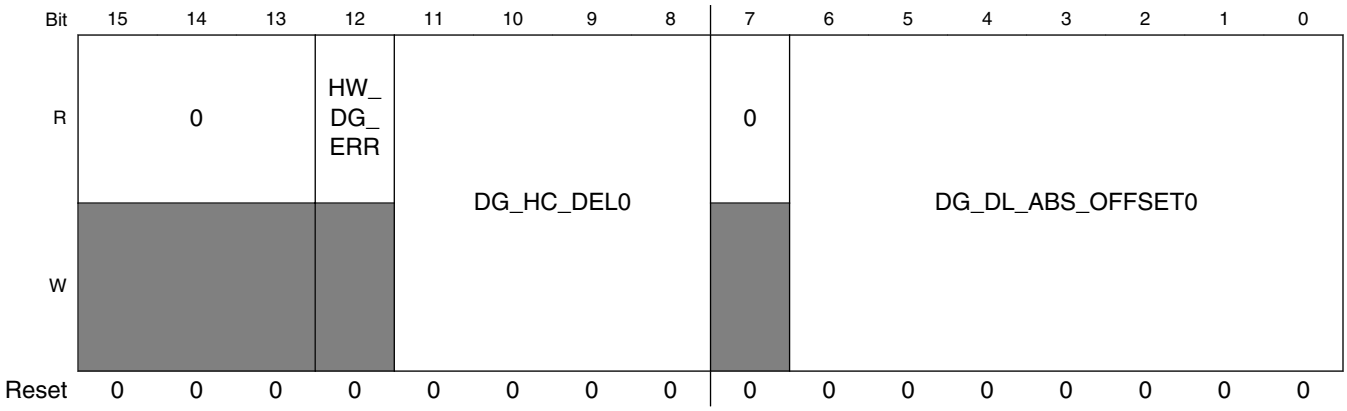
Supported Mode Of Operations:

For Channel 0: DDR3_x16, DDR3_x32, DDR3_x64

For Channel 1: DDR3_x64

Address: Base address + 83Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RST_RD_FIFO	DG_CMP_CYC	DG_DIS	HW_DG_EN	DG_HC_DEL1				DG_EXT_UP	DG_DL_ABS_OFFSET1						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



MMDCx_MPDGCTRL0 field descriptions

Field	Description
31 RST_RD_FIFO	Reset Read Data FIFO and associated pointers. If this bit is asserted then the MMDC resets the read data FIFO and the associated pointers. This bit is self cleared after the FIFO reset is done.
30 DG_CMP_CYC	Read DQS gating sample cycle. If this bit is asserted then the MMDC waits 32 cycles before comparing the read data, Otherwise it waits 16 DDR cycles. 0 MMDC waits 16 DDR cycles 1 MMDC waits 32 DDR cycles
29 DG_DIS	Read DQS gating disable. If this bit is asserted then the MMDC disables the read DQS gating mechanism. If this bits is asserted (read DQS gating is disabled) then pulll-up and pull-down resistors suppose to be used on DQS and DQS# respectively 0 Read DQS gating mechanism is enabled 1 Read DQS gating mechanism is disabled
28 HW_DG_EN	Enable automatic read DQS gating calibration. If this bit is asserted then the MMDC performs automatic read DQS gating calibration. HW negates this bit upon completion of the automatic read DQS gating. Note: Before issuing the first read command the MMDC counts 12 cycles. In LPDDR2 mode automatic (HW) read DQS gating should be disabled and Pull-up/pull-down resistors on DQS/DQS# should be enabled while ODT resistors must be disconnected. 0 Disable automatic read DQS gating calibration 1 Start automatic read DQS gating calibration
27–24 DG_HC_DEL1	Read DQS gating half cycles delay for Byte1 (channel 0 register) and Byte5 in 64-bit mode (channel 1 register) . This field indicates the delay in half cycles between read DQS gate and the middle of the read DQS preamble of Byte1. This delay is added to the delay that is generated by the read DQS1 gating delay-line, So the total read DQS gating delay is (DG_HC_DEL#)*0.5*cycle + (DG_DL_ABS_OFFSET#)*1/256*cycle Upon completion of the automatic read DQS gating calibration this field gets the value of the 4 MSB of ((HW_DG_LOW1 + HW_DG_UP1) /2). 0000 0 cycles delay. 0001 Half cycle delay. 0010 1 cycle delay 1101 6.5 cycles delay

Table continues on the next page...

MMDCx_MPDGCTRL0 field descriptions (continued)

Field	Description
	1110 Reserved 1111 Reserved
23 DG_EXT_UP	DG extend upper boundary. By default the upper boundary of DQS gating HW calibration is set according to first failing comparison after at least one passing comparison. If this bit is asserted then the upper boundary is set according to the last passing comparison.
22–16 DG_DL_ABS_OFFSET1	Absolute read DQS gating delay offset for Byte1. This field indicates the absolute delay between read DQS gate and the middle of the read DQS preamble of Byte1 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (DG_DL_ABS_OFFSET1 / 256)* MMDC_CH0 AXI clock (fast clock). This field can also bit written by HW. Upon completion of the automatic read DQS gating calibration this field gets the value of the 7 LSB of ((HW_DG_LOW1 + HW_DG_UP1) /2). Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 HW_DG_ERR	HW DQS gating error. This bit valid is asserted when an error was found during the read DQS gating HW calibration process. Error can occur when no valid value was found during HW calibration. This bit is valid only after HW_DG_EN is de-asserted. 0 No error was found during the DQS gating HW calibration process. 1 An error was found during the DQS gating HW calibration process.
11–8 DG_HC_DEL0	Read DQS gating half cycles delay for Byte0 (Channel 0 register) and Byte4 in 64-bit mode (Channel 1 register) . This field indicates the delay in half cycles between read DQS gate and the middle of the read DQS preamble of Byte0/4. This delay is added to the delay that is generated by the read DQS1 gating delay-line, So the total read DQS gating delay is (DG_HC_DEL#)*0.5*cycle + (DG_DL_ABS_OFFSET#)*1/256*cycle Upon completion of the automatic read DQS gating calibration this field gets the value of the 4 MSB of ((HW_DG_LOW1 + HW_DG_UP1) /2). 0000 0 cycles delay. 0001 Half cycle delay. 0010 1 cycle delay 1101 6.5 cycles delay 1110 Reserved 1111 Reserved
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DG_DL_ABS_OFFSET0	Absolute read DQS gating delay offset for Byte0. This field indicates the absolute delay between read DQS gate and the middle of the read DQS preamble of Byte0 with fractions of a clock period and up to half cycle.The fraction is process and frequency independent. The delay of the delay-line would be (DG_DL_ABS_OFFSET0 / 256)* MMDC_CH0 AXI clock (fast clock). This field can also bit written by HW. Upon completion of the automatic read DQS gating calibration this field gets the value of the 7 LSB of ((HW_DG_LOW0 + HW_DG_UP0) /2). Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.

44.12.47 MMDC PHY Read DQS Gating Control Register 1 (MMDCx_MPDGCTRL1)

Supported Mode Of Operations:

30–24 RD_DL_ABS_OFFSET3	Absolute read delay offset for Byte3. This field indicates the absolute delay between read DQS strobe and the read data of Byte3 with fractions of a clock period and up to half cycle. The fraction is process and

Table continues on the next page...

MMDCx_MPRDDLCTL field descriptions (continued)

Field	Description
	frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET3 / 256) * MMDC_CH0 AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW3 + HW_RD_DL_UP3) /2 Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 RD_DL_ABS_OFFSET2	Absolute read delay offset for Byte2. This field indicates the absolute delay between read DQS strobe and the read data of Byte2 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET2 / 256) * MMDC_CH0 AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW2 + HW_RD_DL_UP2) /2 Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 RD_DL_ABS_OFFSET1	Absolute read delay offset for Byte1. This field indicates the absolute delay between read DQS strobe and the read data of Byte1 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET1 / 256) * MMDC_CH0 AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW1 + HW_RD_DL_UP1) /2 Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RD_DL_ABS_OFFSET0	Absolute read delay offset for Byte0. This field indicates the absolute delay between read DQS strobe and the read data of Byte0 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET0 / 256) * MMDC_CH0 AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW0 + HW_RD_DL_UP0) /2 Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.

44.12.50 MMDC PHY Read delay-lines Status Register (MMDCx_MPRDDLST)

This register holds the status of the 4 read delay-lines.

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 84Ch offset

MMDCx_MPZQLP2CTL field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–24 ZQ_LP2_HW_ZQCS	This register defines the period in cycles that it takes the memory device to perform a long ZQ calibration. This is the period of time that the MMDC has to wait after sending a short ZQ calibration and before sending other commands. This delay will also be used if ZQ reset is sent. 0x0-0x1A Reserved 0x1B 112 cycles (default) 0x1C 116 cycles 0x7E 508 cycles 0x7F 512 cycles
23–16 ZQ_LP2_HW_ZQCL	This register defines the period in cycles that it takes the memory device to perform a short ZQ calibration. This is the period of time that the MMDC has to wait after sending a long ZQ calibration and before sending other commands. 0x0-0x36 Reserved 0x37 112 cycles 0x38 114 cycles 0x5F 192 cycles (Default, JEDEC value, tZQCL, for LPDDR2, 360ns @ clock frequency 533MHz) 0xFE 510 cycles 0xFF 512 cycles

MMDCx_MPZQLP2CTL field descriptions (continued)

Field	Description
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ZQ_LP2_HW_ZQINIT	This register defines the period in cycles that it takes the memory device to perform a Init ZQ calibration. This is the period of time that the MMDC has to wait after sending a init ZQ calibration and before sending other commands. 0x0-0x36 Reserved 0x37 112 cycles 0x38 114 cycles 0x109 532 cycles (Default, JEDEC value, tZQINIT, for LPDDR2, 1us @ clock frequency 533MHz) 0x1FE 1022 cycles 0x1FF 1024 cycles

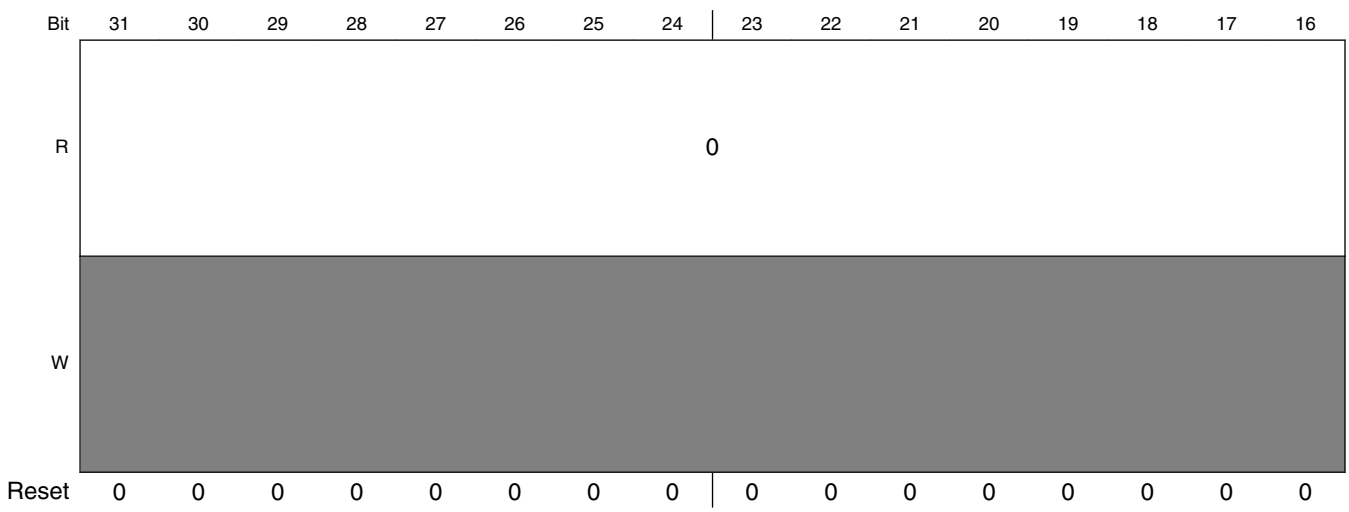
44.12.55 MMDC PHY Read Delay HW Calibration Control Register (MMDCx_MPRDDLHWCTL)

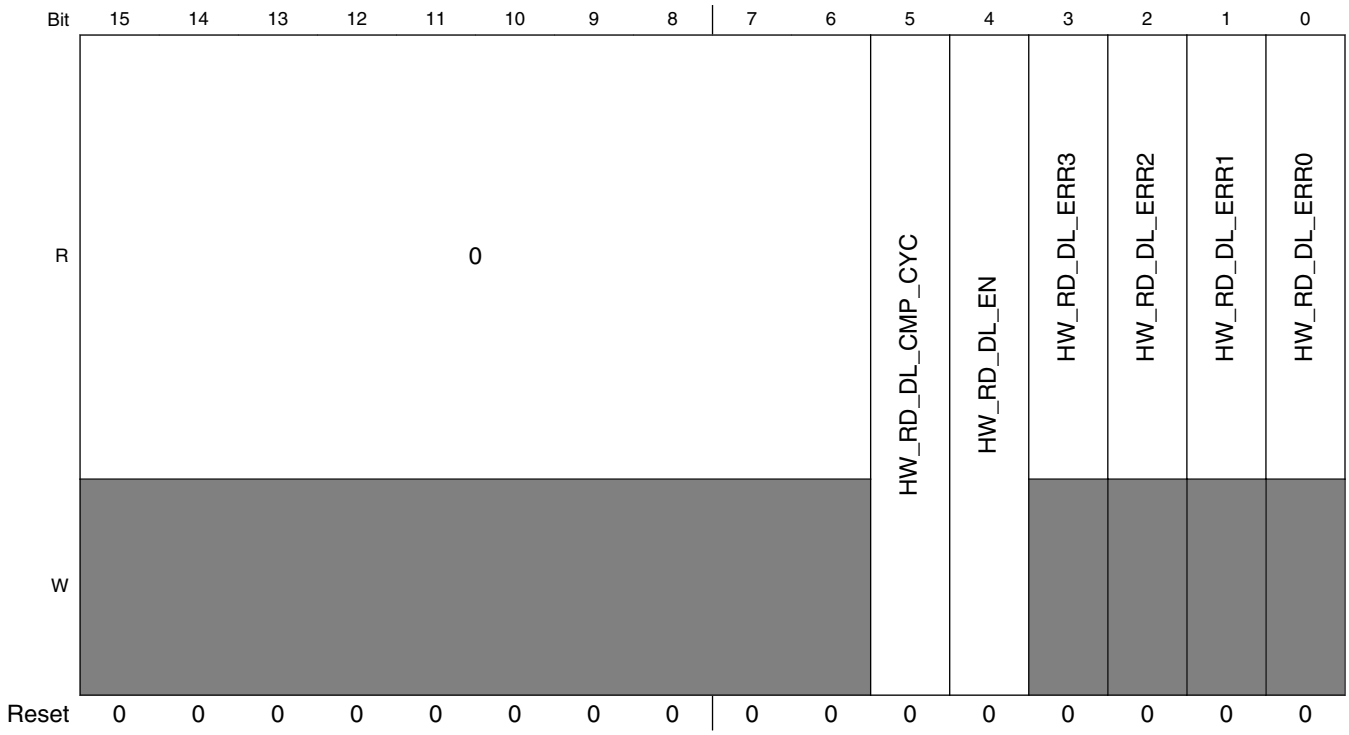
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 860h offset





MMDCx_MPRDDLHWCTL field descriptions

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 HW_RD_DL_ CMP_CYC	Automatic (HW) read sample cycle. If this bit is asserted then the MMDC will compare the read data 32 cycles after the MMDC sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_RD_DL_EN	Enable automatic (HW) read calibration. If this bit is asserted then the MMDC will perform an automatic read calibration. HW should negate this bit upon completion of the calibration. Negation of this bit also points that the read calibration results are valid Note: Before issuing the first read command MMDC counts 12 cycles.
3 HW_RD_DL_ ERR3	Automatic (HW) read calibration error of Byte3. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 3. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay-line 3 during the automatic (HW) read calibration process of read delay-line 3. 1 An error was found in read delay-line 3 during the automatic (HW) read calibration process of read delay-line 3.
2 HW_RD_DL_ ERR2	Automatic (HW) read calibration error of Byte2. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 2. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted.

Table continues on the next page...

MMDCx_MPRDDLHWCTL field descriptions (continued)

Field	Description
	0 No error was found in read delay-line 2 during the automatic (HW) read calibration process of read delay-line 2. 1 An error was found in read delay-line 2 during the automatic (HW) read calibration process of read delay-line 2.
1 HW_RD_DL_ERR1	Automatic (HW) read calibration error of Byte1. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 1. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay-line 1 during the automatic (HW) read calibration process of read delay-line 1. 1 An error was found in read delay-line 1 during the automatic (HW) read calibration process of read delay-line 1.
0 HW_RD_DL_ERR0	Automatic (HW) read calibration error of Byte0. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 0. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay-line 0 during the automatic (HW) read calibration process of read delay-line 0. 1 An error was found in read delay-line 0 during the automatic (HW) read calibration process of read delay-line 0.

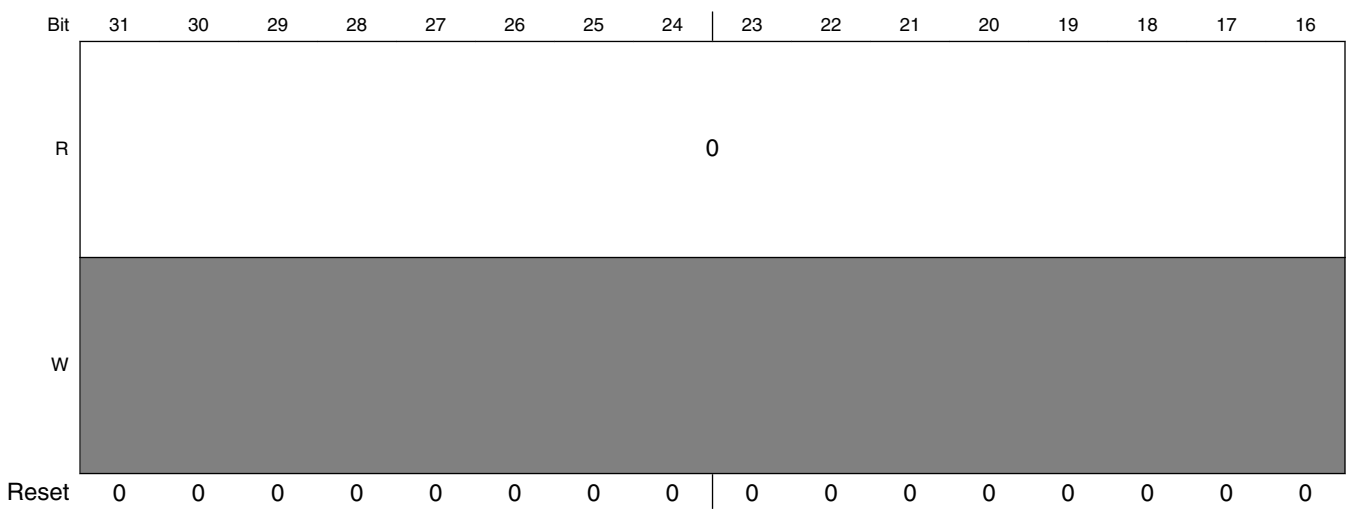
44.12.56 MMDC PHY Write Delay HW Calibration Control Register (MMDCx_MPWRDLHWCTL)

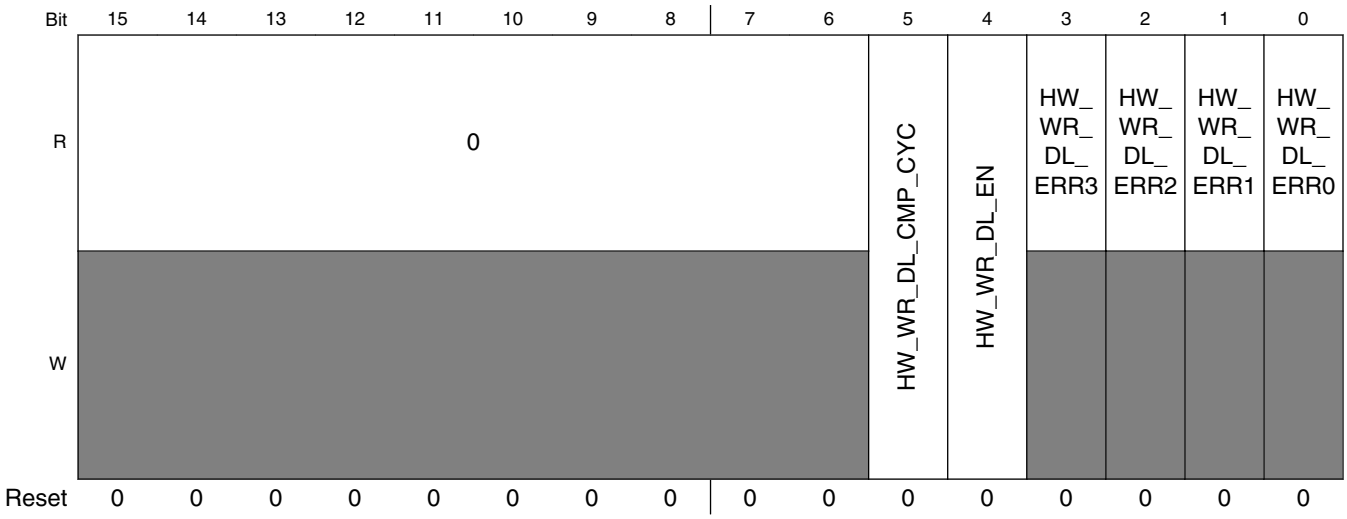
Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 864h offset





MMDCx_MPWRDLHWCTL field descriptions

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 HW_WR_DL_CMP_CYC	Write sample cycle. If this bit is asserted then the MMDC will compare the data 32 cycles after the MMDC sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_WR_DL_EN	Enable automatic (HW) write calibration. If this bit is asserted then the MMDC will perform an automatic write calibration. HW should negate this bit upon completion of the calibration. Negation of this bit also indicates that the write calibration results are valid Note: Before issuing the first read command MMDC counts 12 cycles.
3 HW_WR_DL_ERR3	Automatic (HW) write calibration error of Byte3. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 3. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPWRDLHWST1 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the automatic (HW) write calibration process of write delay-line 3. 1 An error was found during the automatic (HW) write calibration process of write delay-line 3.
2 HW_WR_DL_ERR2	Automatic (HW) write calibration error of Byte2. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 2. T In case this bit is zero at the end of the calibration process then the boundary results can be found at MPWRDLHWST1 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the automatic (HW) write calibration process of write delay-line 2. 1 An error was found during the automatic (HW) write calibration process of write delay-line 2.
1 HW_WR_DL_ERR1	Automatic (HW) write calibration error of Byte1. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 1. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPWRDLHWST0 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the automatic (HW) write calibration process of write delay-line 1. 1 An error was found during the automatic (HW) write calibration process of write delay-line 1.
0 HW_WR_DL_ERR0	Automatic (HW) write calibration error of Byte0. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 0. In case this bit is zero at the end of the

HW_DG_LOW3	HW DQS gating calibration result of the lower boundary of Byte3. This field holds the HW DQS gating calibration result of the lower boundary of Byte3.

44.12.66 MMDC PHY Pre-defined Compare Register 1 (MMDCx_MPPDCMPR1)

This register holds the MMDC pre-defined compare value that will be used during automatic read, read DQS gating and write calibration process. The compare value can be the MPR value (as defined in the JEDEC) or can be programmed by the PDV1 and PDV2 fields. In case of DDR3 (BL=8) the MMDC will duplicate PDV1,PDV2 and drive that data on Beat4-7 of the same byte

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 88Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MMDCx_MPPDCMPR1 field descriptions

Field	Description
31–16 PDV2	MMDC Pre defined compare value2. This field holds the 2 MSB of the data that will be driven to the DDR device during automatic read, read DQS gating and write calibrations in case MPR(DDR3)/ DQ calibration (LPDDR2) mode are disabled (MPR_CMP is disabled). Upon read access during the calibration the MMDC will compare the read data with the data that is stored in this field. Note : Before issue the read access the MMDC will invert the value of this field and drive it to the associate entry in the read comparison FIFO. For further information see Section 19.14.3.1.2, "Calibration with pre-defined value , Section 19.14.4.1.2, "Calibration with pre-defined value and Section 19.14.5.1, "HW (automatic) Write Calibration
PDV1	MMDC Pre defined compare value2. This field holds the 2 LSB of the data that will be driven to the DDR device during automatic read, read DQS gating and write calibrations in case MPR(DDR3)/ DQ calibration (LPDDR2) mode are disabled (MPR_CMP is disabled). Upon read access during the calibration the MMDC will compare the read data with the data that is stored in this field.

Table continues on the next page...

MMDCx_MPPDCMPR1 field descriptions (continued)

Field	Description
	NOTE: Before issuing the read access, the MMDC will invert the value of this field and drive it to the associated entry in the read comparison FIFO.

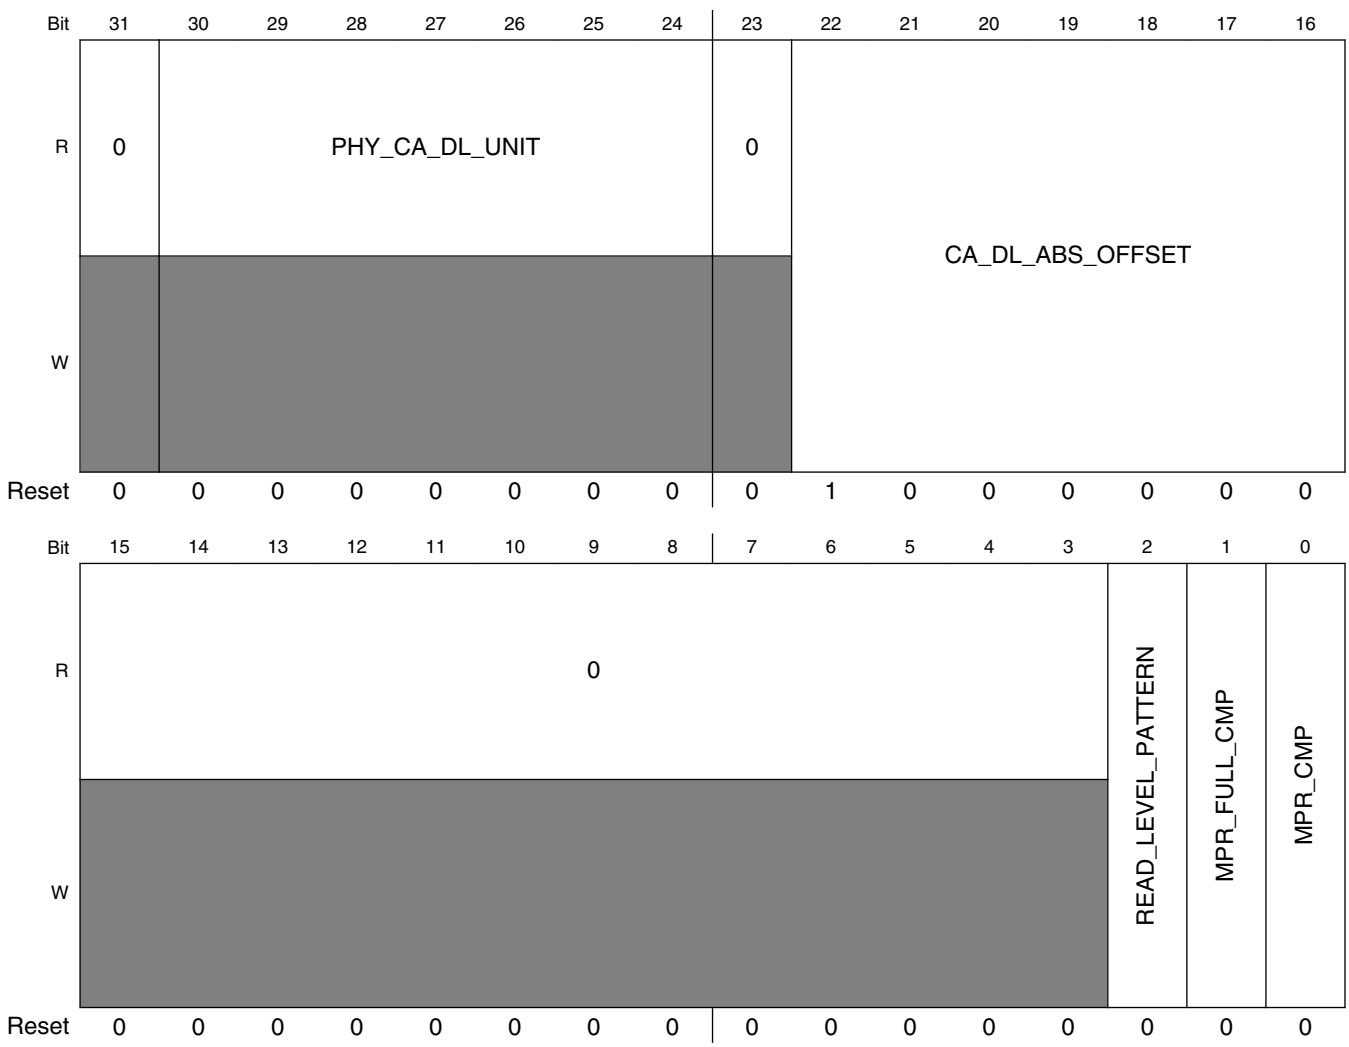
44.12.67 MMDC PHY Pre-defined Compare and CA delay-line Configuration Register (MMDCx_MPPDCMPR2)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 890h offset



MMDCx_MPPDCMPR2 field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–24 PHY_CA_DL_UNIT	This field reflects the number of delay units that are actually used by CA (Command/Address of LPDDR2) delay-line
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 CA_DL_ABS_OFFSET	Absolute CA (Command/Address of LPDDRR2) offset. This field indicates the absolute delay between CA (Command/Address) bus and the DDR clock (CK) with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (CA_DL_ABS_OFFSET / 256) * MMDC_CH0 AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay.
15–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 READ_LEVEL_PATTERN	MPR(DDR3)/DQ calibration(LPDDR2) read compare pattern. In case MPR(DDR3)/DQ calibration(LPDDR2) modes are used during the calibration process (MPR_CMP is asserted) then this field indicates the read pattern for the comparison. 0 Compare with read pattern 1010 1 Compare with read pattern 0011 (Used only in LPDDR2 mode)
1 MPR_FULL_CMP	MPR(DDR3)/DQ calibration (LPDDR2) full compare enable. In case MPR(DDR3)/DQ calibration(LPDDR2) modes are used during the calibration process (MPR_CMP is asserted) then this field indicates whether the MMDC will compare all the bits of the data that is read from the DDR device to the MPR pre-defined pattern. When this bit is de-asserted only LSB of each byte is compared.
0 MPR_CMP	MPR(DDR3)/DQ calibration (LPDDR2) compare enable. This bit indicates whether the MMDC will compare the read data during automatic read and read DQS calibration processes to the pre-defined patterns that are driven by the DDR device (READ_LEVEL_PATTERN as defined by JEDEC) or general pre-defined value that are stored in PDV1 and PDV2. When this bit is disabled data is compared to the data of the pre defined compare value field For further information see Read DQS Gating Calibration and Read Calibration .

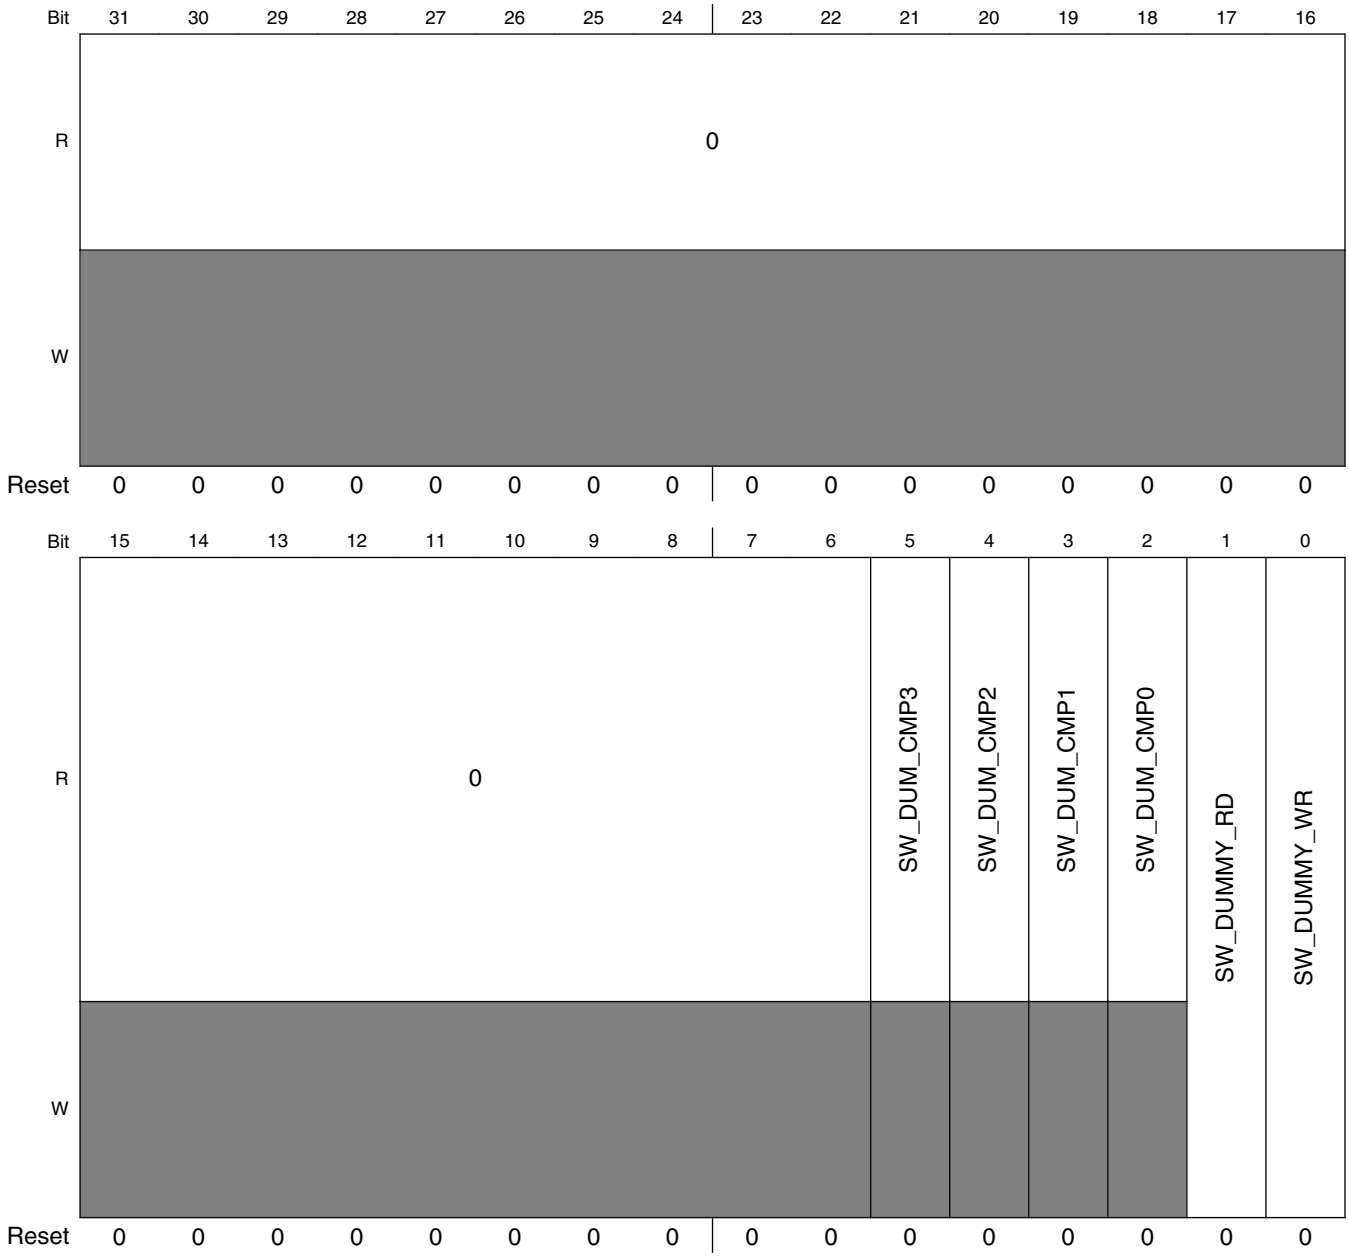
44.12.68 MMDC PHY SW Dummy Access Register (MMDCx_MPSWDAR0)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 894h offset



MMDCx_MPSWDAR0 field descriptions

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SW_DUM_CMP3	SW dummy read byte3 compare results. This bit indicates the result of the read data comparison of Byte3 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-assrted. 0 Dummy read fail 1 Dummy read pass
4 SW_DUM_CMP2	SW dummy read byte2 compare results. This bit indicates the result of the read data comparison of Byte2 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-assrted.

Table continues on the next page...

MMDCx_MPSWDAR0 field descriptions (continued)

Field	Description
	0 Dummy read fail 1 Dummy read pass
3 SW_DUM_CMP1	SW dummy read byte1 compare results. This bit indicates the result of the read data comparison of Byte1 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-assrted. 0 Dummy read fail 1 Dummy read pass
2 SW_DUM_CMP0	SW dummy read byte0 compare results. This bit indicates the result of the read data comparison of Byte0 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-assrted. 0 Dummy read fail 1 Dummy read pass
1 SW_DUMMY_RD	SW dummy read. When this bit is asserted the MMDC will generate internally read access without intervention of the system toward bank 0, row 0, column 0. If MPR_CMP = 1then the read data will be compared to MPPDCMPR2[READ_LEVEL_PATTERN] . If MPR_CMP =0 then the read data will be compared to MPPDCMPR1[PDV1], MPPDCMPR1[PDV2]. Upon completion of the access this bit is de-asserted automatically and the read data and comparison results are valid at MPSWDAR0[SW_DUM_CMP#] and MPSWDRDR0-MPSWDRDR7 respectively.
0 SW_DUMMY_WR	SW dummy write. When this bit is asserted the MMDC will generate internally write access without intervention of the system toward bank 0, row 0, column 0, while the data is driven from MPPDCMPR1[PDV1] and MPPDCMPR1[PDV2]. The bit is de-asserted automatically upon completion of the access.

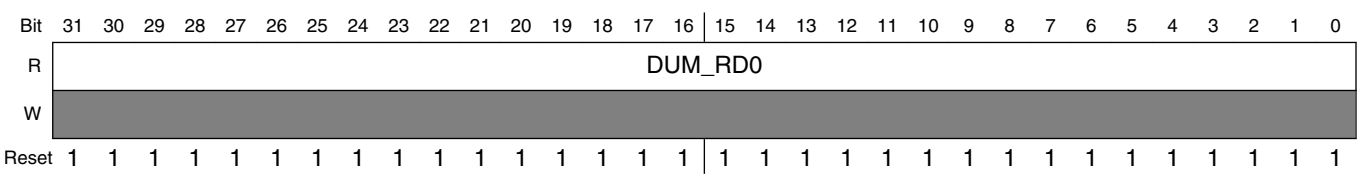
44.12.69 MMDC PHY SW Dummy Read Data Register 0 (MMDCx_MPSWDRDR0)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 898h offset



MMDCx_MPSWDRDR0 field descriptions

Field	Description
DUM_RD0	Dummy read data0. This field holds the first data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-assrted

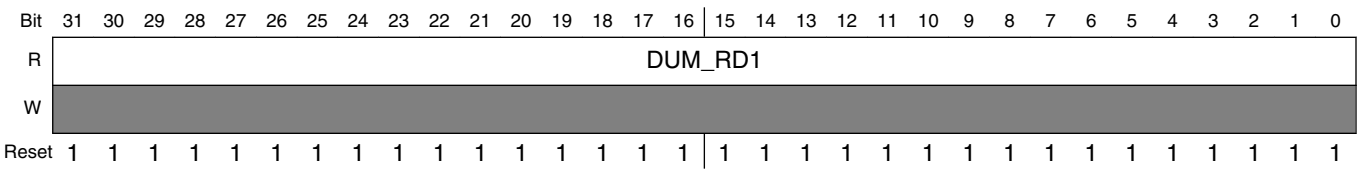
44.12.70 MMDC PHY SW Dummy Read Data Register 1 (MMDCx_MPSWDRDR1)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 89Ch offset



MMDCx_MPSWDRDR1 field descriptions

Field	Description
DUM_RD1	Dummy read data1. This field holds the second data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-assrted

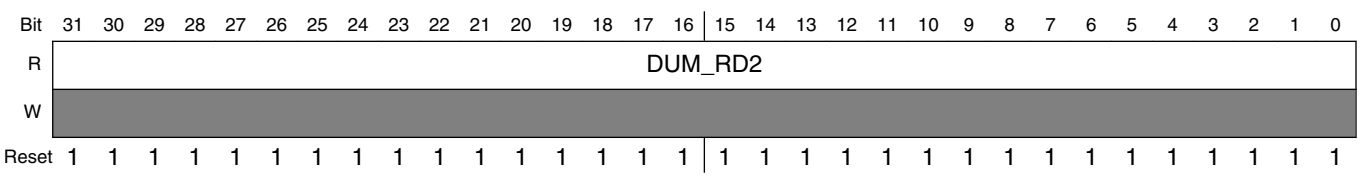
44.12.71 MMDC PHY SW Dummy Read Data Register 2 (MMDCx_MPSWDRDR2)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 8A0h offset



MMDCx_MPSWDRDR2 field descriptions

Field	Description
DUM_RD2	Dummy read data2. This field holds the third data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-assrted.

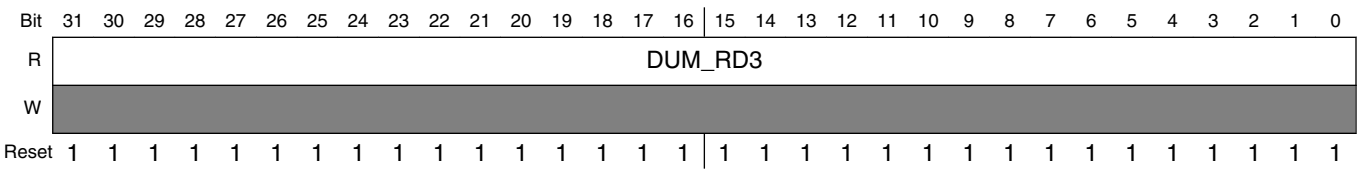
44.12.72 MMDC PHY SW Dummy Read Data Register 3 (MMDCx_MPSWDRDR3)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 8A4h offset



MMDCx_MPSWDRDR3 field descriptions

Field	Description
DUM_RD3	Dummy read data3. This field holds the forth data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-assrted.

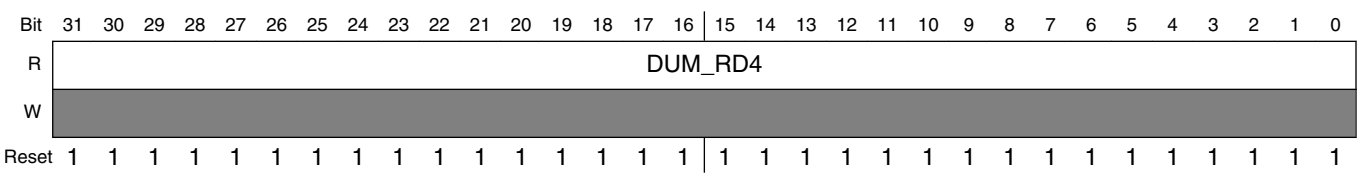
44.12.73 MMDC PHY SW Dummy Read Data Register 4 (MMDCx_MPSWDRDR4)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 8A8h offset



MMDCx_MPSWDRDR4 field descriptions

Field	Description
DUM_RD4	Dummy read data4. This field holds the fifth data (only in case of burst length 8 (BL =1)) that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-assrted.

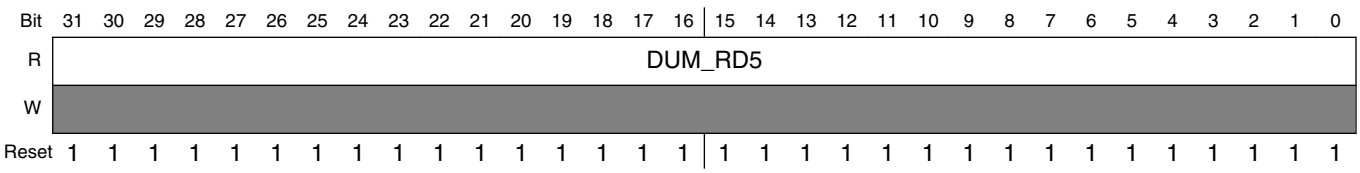
44.12.74 MMDC PHY SW Dummy Read Data Register 5 (MMDCx_MPSWDRDR5)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 8ACh offset



MMDCx_MPSWDRDR5 field descriptions

Field	Description
DUM_RD5	Dummy read data5. This field holds the sixth data (only in case of burst length 8 (BL =1)) that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-assrted.

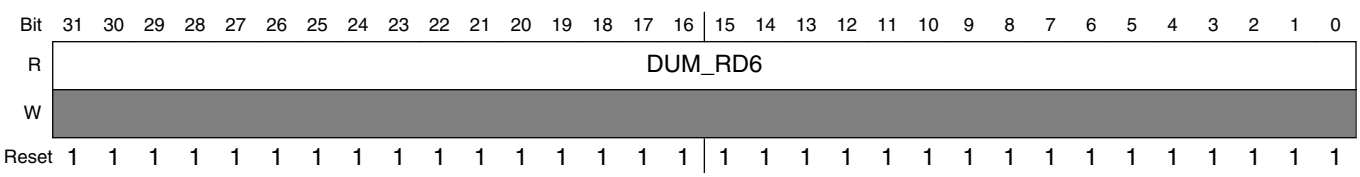
44.12.75 MMDC PHY SW Dummy Read Data Register 6 (MMDCx_MPSWDRDR6)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 8B0h offset



MMDCx_MPSWDRDR6 field descriptions

Field	Description
DUM_RD6	Dummy read data6. This field holds the seventh data (only in case of burst length 8 (BL =1)) that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-assrted.

44.12.76 MMDC PHY SW Dummy Read Data Register 7 (MMDCx_MPSWDRDR7)

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 8B4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MMDCx_MPMUR0 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 MU_UNIT_DEL_NUM	Number of delay units measured per cycle. This field is used in debug mode and holds the number of delay units that were measured by the measure unit per DDR clock cycle. The delay-lines that are used in every calibration process use that number for generating the desired delay.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 FRC_MSR	Force measurement on delay-lines. When this bit is asserted then a measurement process will be performed, where at the completion of the process the delay-lines will issue the desired delay. Upon completion of the measurement process the measure unit and the delay-lines will return to functional mode. This bit is self cleared. **NOTE:** This bit should be used only during manual (SW) calibration and not while the DDR is functional (being accessed). After initial calibration is done the hardware performs periodic measurements to track any operating conditions changes. Hence, force measurements (FRC_MSR) should not be used. See Calibration Process for more information. **NOTE:** User should make sure that there is no active accesses to/from DDR before asserting this bit. 0 No measurement is performed 1 Perform measurement process
10 MU_BYP_EN	Measure unit bypass enable. This field is used in debug mode and when it is asserted then the delay-lines will use the number of delay units that are indicated at MU_BYP_VAL, otherwise the delay-lines will use the number of delay units that was measured by the measurement unit and are indicated at MU_UNIT_DEL_NUM 0 The delay-lines use delay units as indicated at MU_UNIT_DEL_NUM. 1 The delay-lines use delay units as indicated at MU_BYPASS_VAL.
MU_BYP_VAL	Number of delay units for measurement bypass. This field is used in debug mode and holds the number of delay units that will be used by the delay-lines when MU_BYP_EN is asserted.

44.12.78 MMDC Write CA delay-line controller (MMDCx_MPWRCADL)

This register is used to add fine-tuning adjustment to the CA (command/Address of LPDDR2 bus) relative to the DDR clock

Supported Mode Of Operations:

For Channel 0: LP2_2ch_x16, LP2_2ch_x32

For Channel 1: LP2_2ch_x16, LP2_2ch_x32

Address: Base address + 8BCh offset

MMDCx_MPWRCADL field descriptions (continued)

Field	Description
7–6 WR_CA3_DEL	CA (Command/Address LPDDR2 bus) bit 3 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 3 relative to the clock. 00 No change in CA3 delay 01 Add CA3 delay of 1 delay unit 10 Add CA3 delay of 2 delay units. 11 Add CA3 delay of 3 delay units.
5–4 WR_CA2_DEL	CA (Command/Address LPDDR2 bus) bit 2 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 2 relative to the clock. 00 No change in CA2 delay 01 Add CA2 delay of 1 delay unit 10 Add CA2 delay of 2 delay units. 11 Add CA2 delay of 3 delay units.
3–2 WR_CA1_DEL	CA (Command/Address LPDDR2 bus) bit 1 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 1 relative to the clock. 00 No change in CA1 delay 01 Add CA1 delay of 1 delay unit 10 Add CA1 delay of 2 delay units. 11 Add CA1 delay of 3 delay units.
WR_CA0_DEL	CA (Command/Address LPDDR2 bus) bit 0 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 0 relative to the clock. 00 No change in CA0 delay 01 Add CA0 delay of 1 delay unit 10 Add CA0 delay of 2 delay units. 11 Add CA0 delay of 3 delay units.

44.12.79 MMDC Duty Cycle Control Register (MMDCx_MPDCCR)

This register is used to control the duty cycle of the DQS and the primary clock (CK0) . Programming of that register is permitted by entering the DDR device into self-refresh mode through LPMD/DVFS mechanism

Supported Mode Of Operations:

For Channel 0: All

For Channel 1: DDR3_x64, LP2_2ch_x16, LP2_2ch_x32

NOTE

If the duty cycle is modified after DDR initialization, the DDR will have to be placed in self-refresh mode.

NOTE

The duty cycle may be changed during initial DDR initialization without having to be placed in self-refresh mode.

Address: Base address + 8C0h offset

Chapter 45
Network Interconnect Bus System (NIC-301)

45.1 Overview

This section provides an overview of the NIC-301 (Network Inter-Connect) AXI arbiter IP.

The NIC-301 (by ARM Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 functionality, while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the ARM specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual*.

NOTE

The NIC-301 default settings are configured by Freescale's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

45.1.1 Block diagram

The NIC-301 AXI arbiter (or "CoreLink Network Interconnect") by ARM, provides configurable AXI-based interconnect logic, for connecting a number of masters (initiators) to several slaves (targets), via a configurable bus switches and bridging components.

The bus system is composed of five such instances: PER1, PER2, FAST1, FAST2, and FAST3.

Each instance can include one or more bus switches, with additional logic.

This chapter provides details of the various instances and the selected configuration parameters.

The top level diagram of the bus system is shown in the following figure.

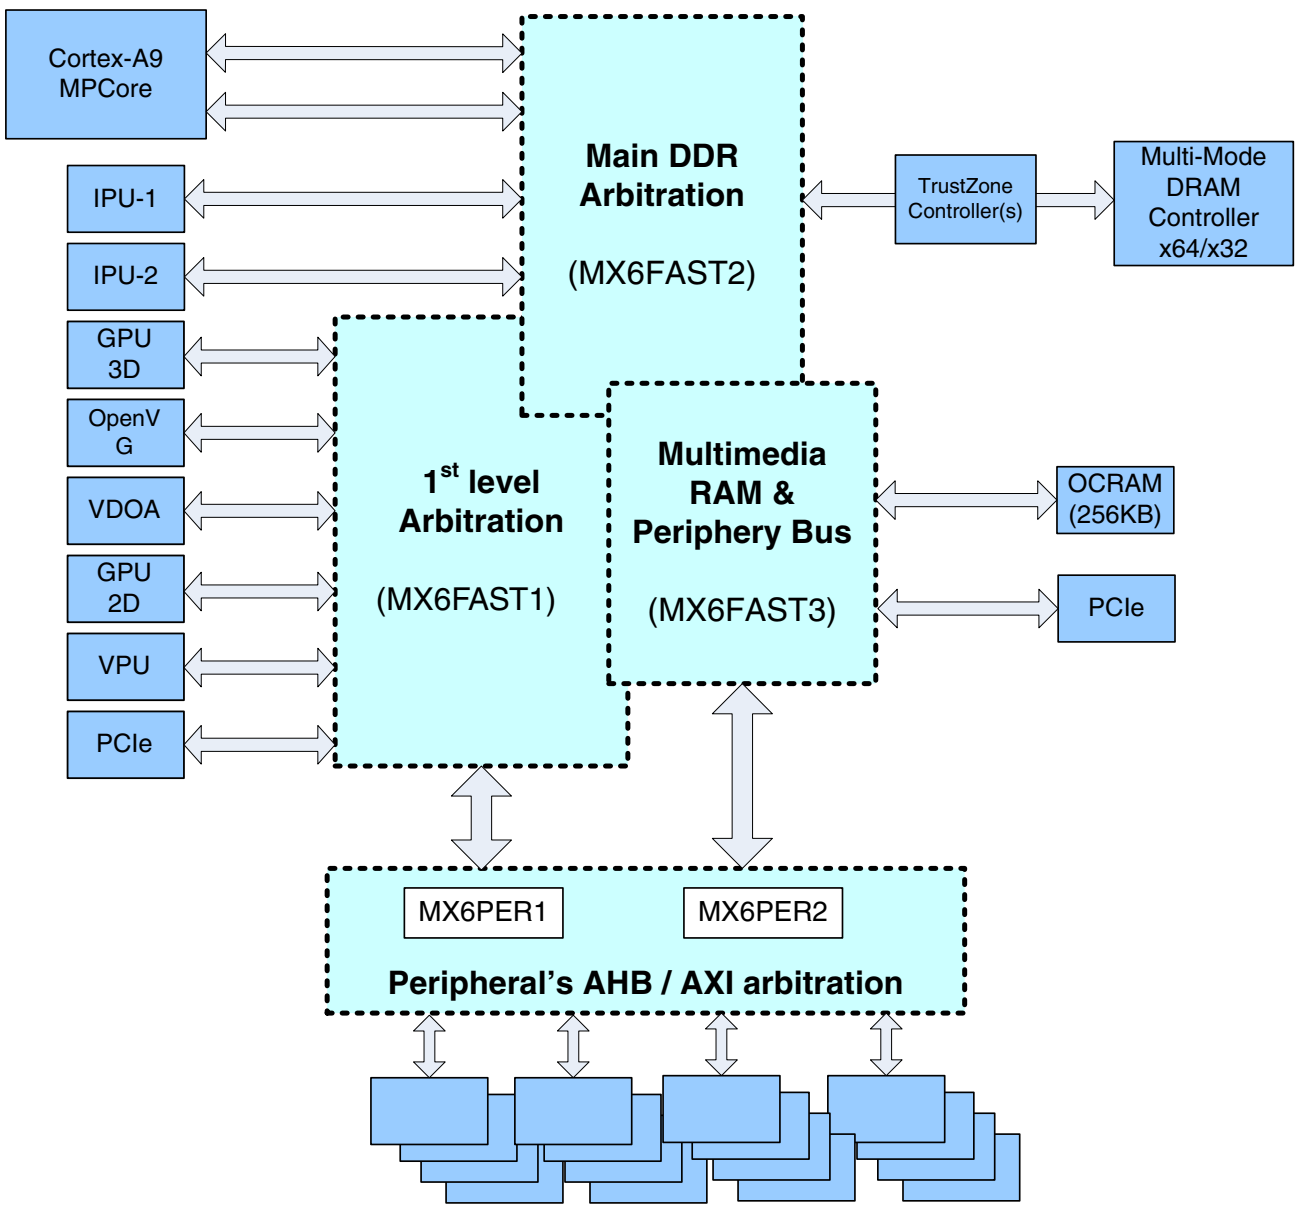

Figure 45-1. NIC-301 Bus System

45.1.2 NIC-301 Main Features

Key features of the NIC-301 module include the following:

- Address space memory mapping, including 'remap' functions.
- Programmer's view, for software-configured parameters, via "GPV" ports.
- Support for cross-clock domain synchronization.

45.1.3 Modes and Operations

The NIC-301 supports a normal functional mode only, as described in Normal Mode.

45.2 External Signals

The NIC-301 has no external I/O interfaces.

45.3 Memory Map and Register Definition

This section includes the block memory map and detailed register descriptions.

Access to NIC-301 registers is provided through the global programmer's view (GPV) ports. Each GPV port provides access to the configuration registers of certain IP as listed in Table 45-5 . The GPV base addresses are listed in the table below:

Table 45-1. GPV ports memory allocations

GPV	Associated NIC-301	System Bus	Chip Address	
			Start	End
GPV_0	FAST2	Main DDR Arbitration	00B0_0000	00BF_FFFF
GPV_1	FAST1	First Level Arbitration	00C0_0000	00CF_FFFF
GPV_2	PER1	Peripheral's AHB/AXI Arbitration	0020_0000	002F_FFFF
GPV_3	PER2	Reserved (Internal Use Only)	0030_0000	003F_FFFF
GPV_4	FAST3	Multimedia RAM and Peripheral Bus	0080_0000	008F_FFFF

45.3.1 Memory Map

The NIC-301 memory map, is dependent on the selected configuration option at time of creation.

A "template" map is provided in Table 45-2 below. For specific features, see the configuration tables in NIC-specific parameters to check whether specific options are selected.

45.3.2 Configuration programmers model

The GPV's contain configuration registers, partitioned into a number of individual 4KB blocks.

The general structure of the registers is provided by the following tables:

- Address map of the programmers model, Table 45-2
- AMIB Registers, Table 45-3
- ASIB Registers, Table 45-4

Table 45-2. Address map of the programmers model

Address Offset from Base Address	Registers	Notes
0x000F_F000	Internal interface p registers	Maximum p = 61
	...	Note [1]
0x000C_4000	Internal interface 2 registers	
0x000C_3000	Internal interface 1 registers	
0x000C_2000	Internal interface 0 registers	
0x000C_1000	Slave interface m registers	Maximum m = 127
	...	Note [2]
0x0004_4000	Slave interface 2 registers	
0x0004_3000	Slave interface 1 registers	
0x0004_2000	Slave interface 0 registers	
0x0004_1000	Master interface n registers	Maximum n = 63
	...	Note [3]
0x0000_4000	Master interface 2 registers	
0x0000_3000	Master interface 1 registers	
0x0000_2000	Master interface 0 registers	
0x0000_1000	ID registers	
0x0000_0000	Address control registers	Configurable base address [4]

1. Index refers to BI registers index
2. Index refer to ASIB registers index
3. Index refer to AMIB registers index

4. Reserved for internal use

45.3.2.1 Address control and ID registers

Registers at offsets 0x0–0xFFC are reserved for internal use.

45.3.2.2 AMBA master interface block (AMIB) configuration registers

The table below lists only the registers that affect the user. All other addresses are treated as "reserved".

Table 45-3. AMIB Registers

Offset	Register	Access	Width	Reset Value
0x024	fn_mod2 Bypass merge. This register is only present if upsizing or downsizing. See upsizing/downsizing data width functions in AMBA Network Interconnect TRM.	RW	1	0
0x040	wr_tidemark	RW	4	Note [1]

1. Reset value varies, default value chosen at RTL creation time is designed to suit normal operation.

45.3.2.3 ASIB (AMBA slave interface block) configuration registers

The table below lists only the registers that affect the user. All other addresses are treated as "reserved".

Table 45-4. ASIB Registers

Offset	Register	Access	Width	Reset Value
0x040	wr_tidemark Valid only for AXI slaves with WFIFO >=4.	RW	1	Note [1]
0x100	read_qos	RW	4	Note [2]
0x104	write_qos	RW	4	Note [3]

1. Reset value varies, default value chosen at RTL creation time is designed to suit typical operation cases.
2. QoS default is set at RTL creation time, and is listed in specific NIC-301 configuration tables in NIC-specific parameters, as parameters "QoS qv_value" in ASIB / AMIB parameter tables.
3. QoS default is set at RTL creation time, and is listed in specific NIC-301 configuration tables in NIC-specific parameters, as parameters "QoS qv_value" in ASIB / AMIB parameter tables.

45.3.3 Register Descriptions

The NIC-301 registers are dependent upon the selected configuration, the type of ports, hardware-selected features and whether they have a GPV view. The addressing is associated to a specific port, by looking at the port's index number, under "apb_slave" column.

The memory map template is provided in the Configuration programmers model above.

45.3.3.1 QoS registers' address look-up example

The flow below describes the steps needed in determining the memory addresses for GPU3D QoS read/write registers:

- Look up the GPU3D port indexes ("apb_slave"[1] column in Table 45-5): index 66 and 71 for primary and secondary buses, respectively. Note that the GPU3D is listed under GPV_1 interface.
- Look up the GPV_1 base address: 0x00C0_0000, in Table 45-1 .
- The master/slave ports configuration base address, is always obtained by: "GPV base" + ("APB index" x 0x1000), regardless of whether it is a slave or a master port. This is somewhat contrary to the way indexes are presented in the "Address map of the NIC-301 programmers model" in the ARM documentation as shown in Table 45-2, where, instead, the indexes are provided in absolute values (of 0x1000 jumps), starting from the GPV base address.

  Hence, for the GPU3Dprimary port (index '66'), the "slave interface" programming base address is 0x00C4_2000 (= GPV_1 base + 66 x 0x1000).

  Similarly, for the GPU3D's secondary port (index 71), the "slave interface" programming base address is 0x00C4_7000 (= GPV_1 base + 71 x 0x1000).

- To access any of the slave/master interface registers (in this example - the QoS read/write ones), their offset(s) must be added, as shown in Table 45-4 :

  "0x100" for Read_QoS and "0x104" for Write_QoS, in our example.

Final addresses obtained for QoS registers for the GPU3D primary port (index 66), are as follows:

- Read QoS: "0x00C4_2100"
- Write QoS: "0x00C4_2104"

1. The "slave", "master" type is assumed from NIC-301 point of view.

Similarly, QoS registers addresses for the GPU3D secondary port (index 71), are as follows:

- Read QoS: "0x00C4_7100"
- Write QoS: "0x00C4_7104"

45.3.4 NIC-specific parameters

This section details the configuration parameters of the NIC-301.

General notes:

1. All accesses to GPV_4 port, must be of "Supervisor" type.
2. The associated master/slave port interface ID (for each "GPV_N") is specified by the "apb_slave" / "apb_master" [2] index. The slave/master interface, configuration register's start address is obtained by the following:

   Start address (for "apb" index= "n") = GPV_N base + (n x 0x1000).

3. The security features of NIC-301 are not used, since master-slaves permissions are controlled by the CSU security policy/scheme.

Table 45-5. QoS and tidemark parameters

Master	apb_slave	Tidemark	QOS qv_value	Comments
Configured via GPV_1 port				
GPU3D (Primary)	66	2	2	
GPU3D (Secondary)	71	2	2	
GPU2D (Primary)	67	2	2	
GPU2D (Secondary)	72	2	2	
VDOA	68	2	2	
OpenVG	69	2	2	
VPU Prim.	73	2	2	
PCIe	74	2	2	
Configured via GPV_0 port				
MPCore-0	66		2	
MPCore-1	67		2	
IPU1	68	4	0	QoS configurable via GPR bits in IOMUXC.
IPU2	69	4	0	QoS configurable via GPR bits in IOMUXC.
Configured via GPV_4 port				
VPU	68		2	

Table continues on the next page...

2. "APB" stands for "ARM Peripheral Bus".

Chapter 46
On-Chip OTP Controller (OCOTP_CTRL)

46.1 Overview

This section contains information describing the requirements for the on-chip eFuse OTP controller along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

46.1.1 Features

The OCOTP provides the following features :

- 32-bit word restricted program and read to 4 kbit of eFuse OTP(512 x 8).
- Loading and housing of fuse content into shadow registers.
- Memory-mapped (restricted) access to 4 kbit of shadow registers.
- Generation of HWV_FUSE (hardware visible fuse bus) and the HWV_REG bus which is made of up of volatile PIO register based "fuses". The HWV_REG bits come from the SCS (Software Controllable Signals) register.
- Generation of STICKY_REG which is consist of sticky register bits.
- Provide program-protect and read-protect eFuse.
- Provide override and read protection of shadow register.
- CRC32 test for read-lock fuse content.

46.2 Clocks

The table found here describes the clock sources for OCOTP.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 46-1. OCOTP Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

46.3 Top-Level Symbol and Functional Overview

The figure found here shows the OCOTP system level diagram.

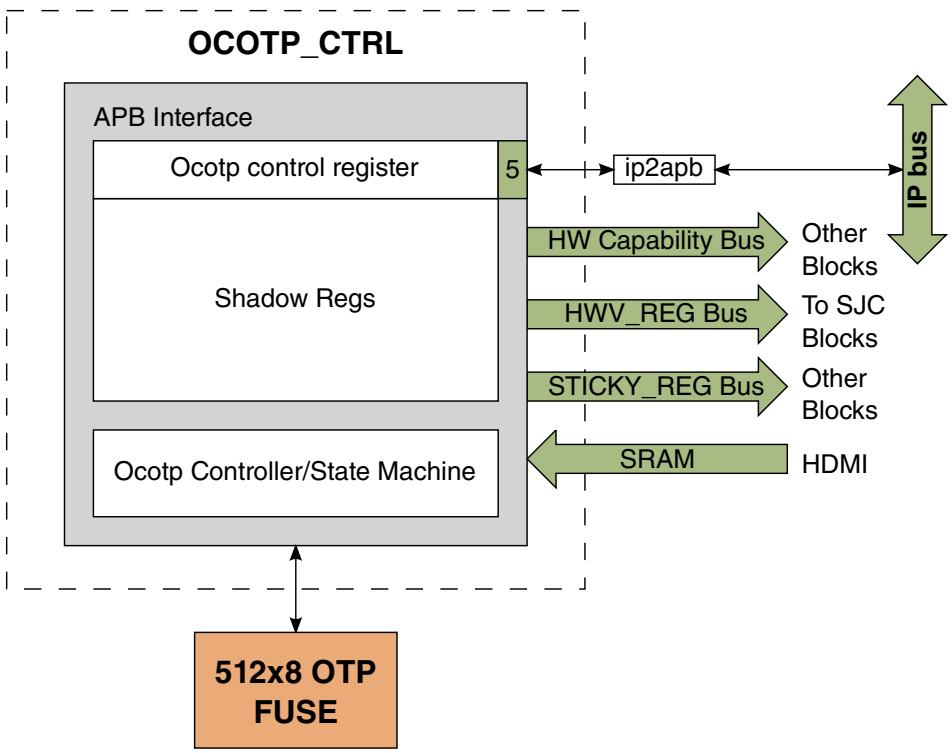

Figure 46-1. OCOTP System Level Diagram

46.3.1 Operation

The IP bus interface of the OCOTP provides two functions.

- Configure control registers for programming and reading fuse word.
- Override and read shadow registers.

For efuse, program can only be performed on bit and read is based on byte. OCOTP configuration for program and read are performed on 32-bit words for SW convenience. For writes, the 32-bit word reflects the "write-mask". Bit fields with 0 will not be programmed and bit fields with 1 will be programmed. OCOTP will program bit field with 1 in the fuse word one bit by one bit. For reads, OCOTP will read 4 times to get 4 bytes in the fuse word in order.

In this document, 4-kbit fuse are divided into 16 banks by function. Each bank has 8 fuse words. In physical, 4k bits fuse are in one 512x8 efusebox.

46.3.1.1 Shadow Register Reload

All fuse words in efusebox are shadowed. Therefore, fuse information is available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers (including HW_OCOTP_LOCK) without having to reset the device. To force a reload, complete the following steps:

1. Set the HW_OCOTP_TIMING[STROBE_READ] and HW_OCOTP_TIMING[RELAX] field value appropriately (as explained in a later section).
2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write , read or reload must be completed before a new access can be requested.
3. Set the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit. OCOTP will read all the fuse one by one and put it into corresponding shadow register.
4. Wait for HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[RELOAD_SHADOWS] to be cleared by the controller.

The controller will automatically clear the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

46.3.1.2 Fuse and Shadow register read

All shadow registers are always readable through the APB bus except some secret keys regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write , read or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

To read fuse words directly from fusebox correctly complete the following steps:

1. Program HW_OCOTP_TIMING[STROBE_READ] and HW_OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the ipg_clk. OTP read will work at maximum bus frequencies as long as the HW_OCOTP_TIMING parameters are set correctly.
2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
3. Write the requested address to HW_OCOTP_CTRL[ADDR].
4. Set HW_OCOTP_READ_CTRL[READ_FUSE] to 1. OCOTP will auto read 4 bytes in requested word address in fusebox one by one. Then put read value into HW_OCOTP_READ_FUSE_DATA register.
5. Once complete, the controller will clear BUSY. A read request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read HW_OCOTP_READ_FUSE_DATA register to get fuse word value.HW_OCOTP_READ_FUSE_DATA will be 0xBADABADA when HW_OCOTP_CTRL[ERROR] is set.

46.3.1.3 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The LOCK shadow register also has no shadow or fuse lock bits but it is always read only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank correctly complete the following steps:

1. Program HW_OCOTP_TIMING[STROBE_PROG] and HW_OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the ipg_clk. OTP writes will work at maximum bus frequencies as long as the HW_OCOTP_TIMING parameters are set correctly.

2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested address to HW_OCOTP_CTRL[ADDR] and program the unlock code into HW_OCOTP_CTRL[WR_UNLOCK]. This must be programmed for each write access. The lock code is documented in the register description. Both the unlock code and address can be written in the same operation.
4. Write the data to the HW_OCOTP_DATA register. This will automatically set HW_OCOTP_CTRL[BUSY] and clear HW_OCOTP_CTRL[WR_UNLOCK]. To protect programming same OTP bit twice, before program OCOTP will automatically read fuse value in OTP and use read value to mask program data. The controller will use masked program data to program a 32-bit word in the OTP per the address in HW_OCOTP_CTRL[ADDR]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of HW_OCOTP_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to HW_OCOTP_CTRL[ADDR] will not affect an active write operation. It should also be noted that during the programming HW_OCOTP_DATA will shift right (with zero fill). This shifting is required to program the OTP serially. During the write operation, HW_OCOTP_DATA cannot be modified.
5. Once complete, the controller will clear BUSY. A write request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds per word. Write latencies is based on amount of bit filed which is 1. For example : program half fuse bits in one word need 10 us x 16.

For further details of OTP read/write operations see [eFUSE].

HW_OCOTP_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while HW_OCOTP_CTRL[RELOAD_SHADOWS] is set. In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed to from a shadow register which has been read locked.
- A program is performed to a fuse word which has been locked.
- A read is performed to from a fuse word which has been read locked.

46.3.1.4 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations following a write must be separated by 2 us after the clearing of HW_OCOTP_CTRL_BUSY following the write. This guarantees programming voltages on-chip to reach a steady state when exiting a write sequence. This includes reads, shadow reloads, or other writes.

A recommended software sequence to meet the postamble requirements is as follows:

- Issue the write and poll for BUSY (as per Fuse Shadow Memory Footprint).
- Once BUSY is clear, use HW_DIGCTL_MICROSECONDS to wait 2 us.
- Perform the next OTP operation.

46.3.2 Fuse Shadow Memory Footprint

The OTP memory footprint shows in the following figure. The registers are grouped by lock region. Their names correspond to the PIO register and fusemap names.

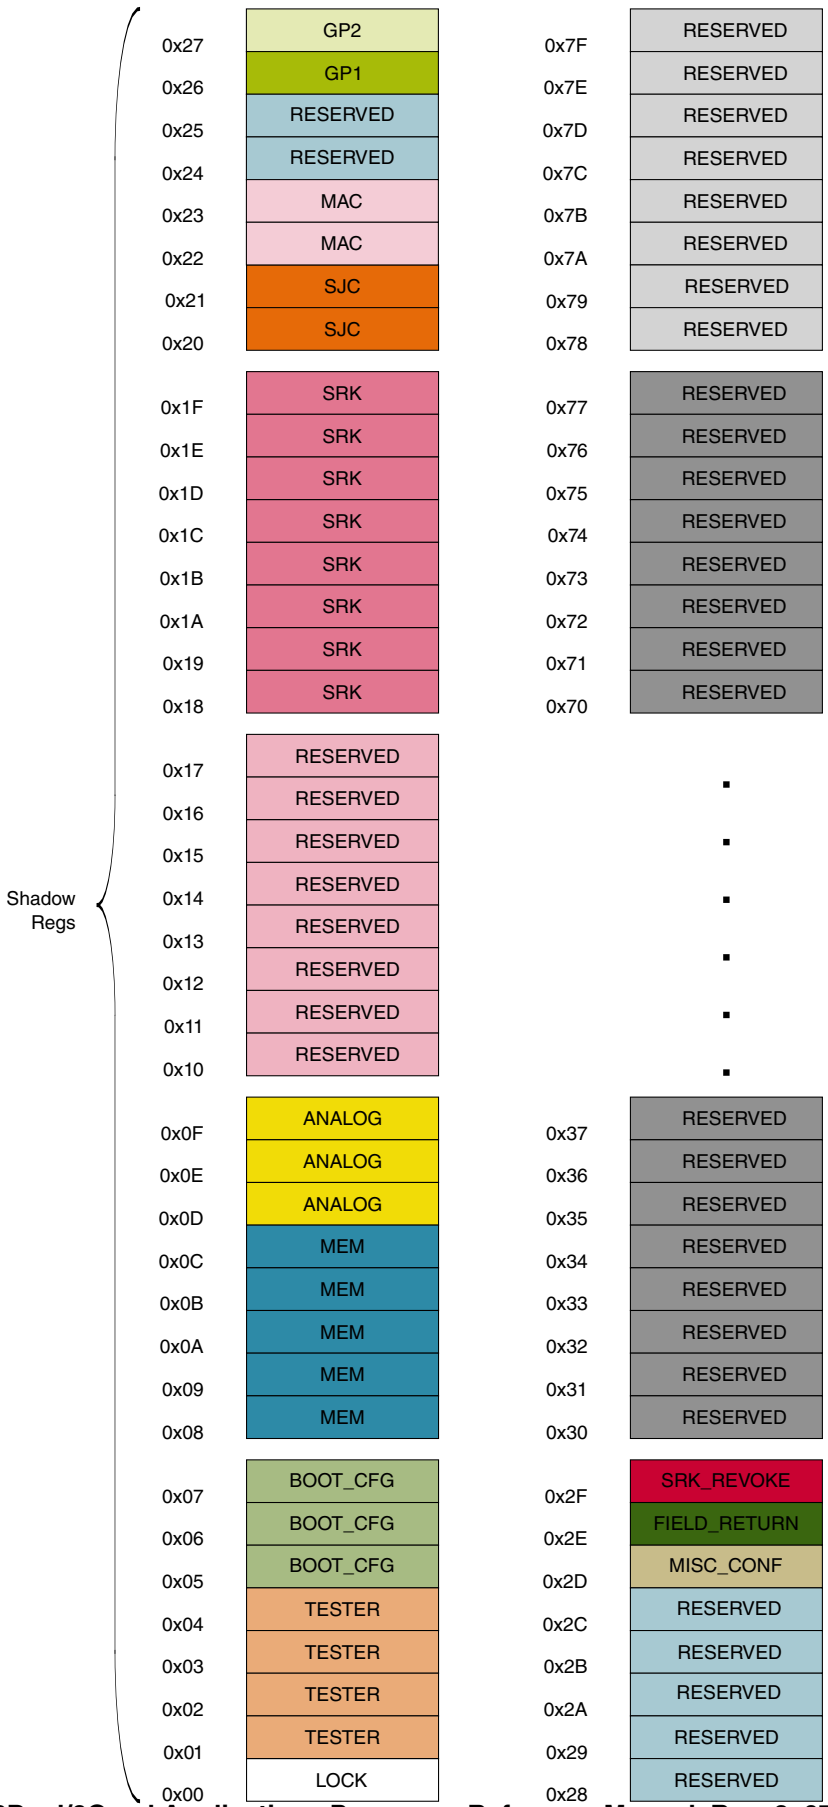

Figure 46-2. OTP Memory Footprint

46.3.3 OTP Read/Write Timing Parameters

There are three timing fields contained in the HW_OCOTP_TIMING register that specify counter limit values, which are used to time how long the state machine remains in the various states, as well as specify the STROBE signal timing.

TheyBoth two timing parameters are all specified in ipg_clk cycles. Since the ipg_clk frequency can be set to a range of values, these parameters must be adjusted with the clock to yield the appropriate delay.

The HW_OCOTP_TIMING[RELAX] field specifies how long to remain in states to meet setup and hold timing requirement in fuse spec. This parameter should be set by the following equation:

tRELAX = tHP_PG = (HW_OCOTP_TIMING[RELAX]+1)/ipg_frequency > 16.2ns

HW_OCOTP_TIMING[RELAX] field is used to create other setup and hold timing delays in addition to tHP_PG. For all timing to be met, this is the max delay that must be programmed.

Except for setup and hold timing delay, there are 2 timing parameters for STROBE signal pulse width in program and read.

The HW_OCOTP_TIMING[STROBE_PROG] field specifies the period of the STROBE signal for fuse writes and is given in units of ipg_clk cycles. This value should be specified so that the requirement for the time when the STROBE signal is asserted high is met: 9000ns < tPGM < 11000ns is met. Even though a range is given for tPGM, it is advised in **[eFUSE]** to program for a value of 10000ns. Therefore, this field should be set according to the following equation:

tPGM = ((HW_OCOTP_TIMING[STROBE_PROG]+1)-
2*(HW_OCOTP_TIMING[RELAX]+1))/ipg_frequency = 10000ns.

The HW_OCOTP_TIMING[STROBE_READ] field specifies the period of the STROBE signal for fuse reads and is given in units of ipg_clk cycles. This field should be set according to the following equation:

tRD = ((HW_OCOTP_TIMING[STROBE_READ]+1)-
2*(HW_OCOTP_TIMING[RELAX]+1))/ipg_frequency > 36ns.

The figure below illustrates the relationship between the STROBE signal in programming and reading mode, as well as the timing PIO register fields that affect it. The implementation uses one counter to generate the STROBE waveform within one period and a second counter counts the number of cycles to create for programming the designated word.

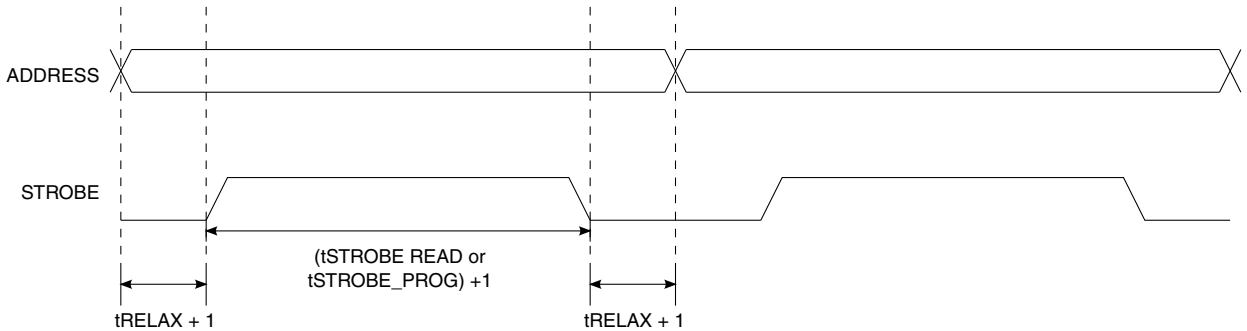

Figure 46-3. STROBE Signal Creation and Timing

46.3.4 Hardware Visible Fuses

The hwv_fuse bus emanates from the OCOTP block and goes to various other blocks inside the chip. This bus is made up of the shadow register bits for banks 0, 1, 2 and 4.

Only a subset of these fuse bits are currently used by the hardware. The fuse bits are initially copied from the eFuse banks after reset is deasserted. When all fuse bits are loaded into their shadow registers, the OCOTP asserts the fuse_latched output signal.

The hwv_reg bus also comes from the OCOTP. Its source is the HW_OCOTP_SCS register. This register has 1 defined bit, the HAB_JDE bit, that is connected to the SJC block. The SCS bits are intended to be used as volatile fuse bits under software control. Additional bits will be defined as needed in future implementations.

The system-wide reset sequence must be coordinated by the system reset controller, so that the hwv_fuse and hwv_reg buses are stable and reflect the values of the fuses before they are used by the rest of the system.

46.3.5 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time HW_OCOTP_CTRL_BUSY is set. The load time is similar to that of a "reload shadow" operation.

46.3.6 Secure JTAG control

The JTAG control fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are envisioned, as shown in the table below.

Table 46-2. JTAG Security Level Control Bits

Security Mode	JTAG_SMODE	Description
No Debug	2'b11	The highest security level.
Secure JTAG	2'b01	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	Low Security, all JTAG features are enabled.

46.4 Fuse Map

See the Fusemap chapter of this reference manual for more information.

46.5 OCOTP Memory Map/Register Definition

OCOTP Hardware Register Format Summary

OCOTP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
21B_C000	OTP Controller Control Register (OCOTP_CTRL)	32	R/W	0000_0000h	46.5.1/4030
21B_C004	OTP Controller Control Register (OCOTP_CTRL_SET)	32	R/W	0000_0000h	46.5.1/4030

46.5.1 OTP Controller Control Register (OCOTP_CTRL*n*)

The OCOTP Control and Status Register specifies the copy state, as well as the control required for random access of the OTP memory

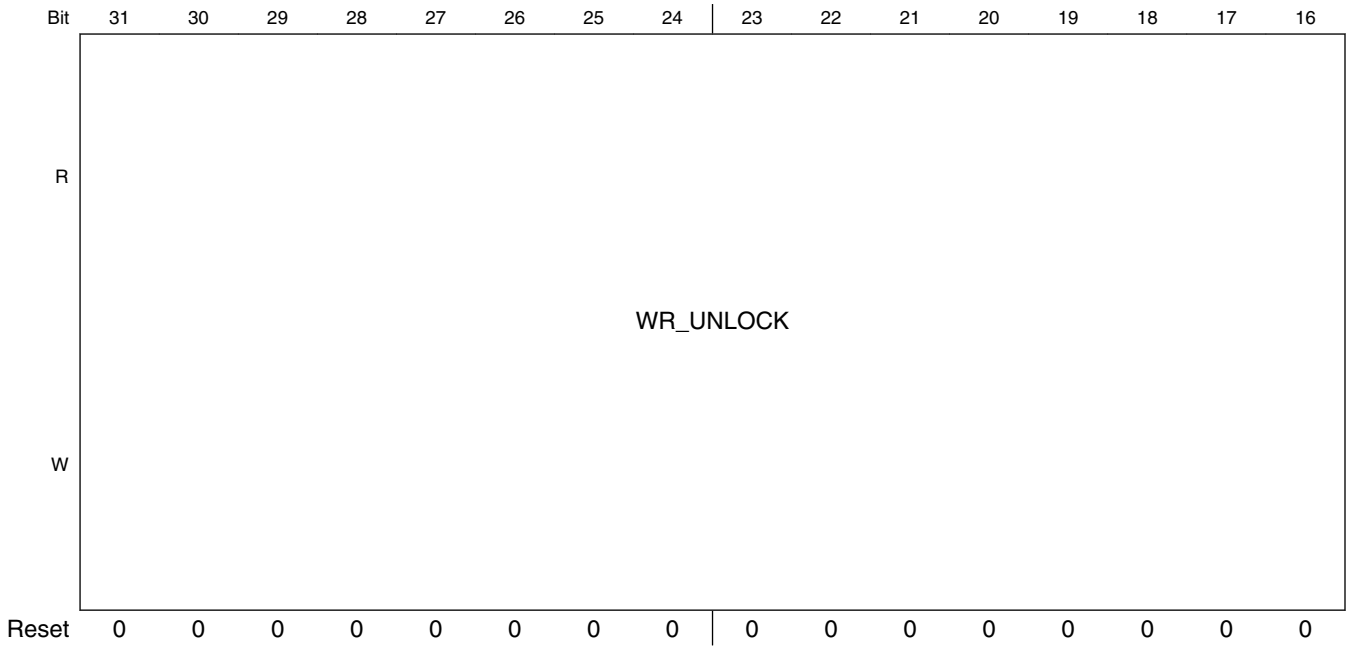
OCOTP_CTRL: 0x000

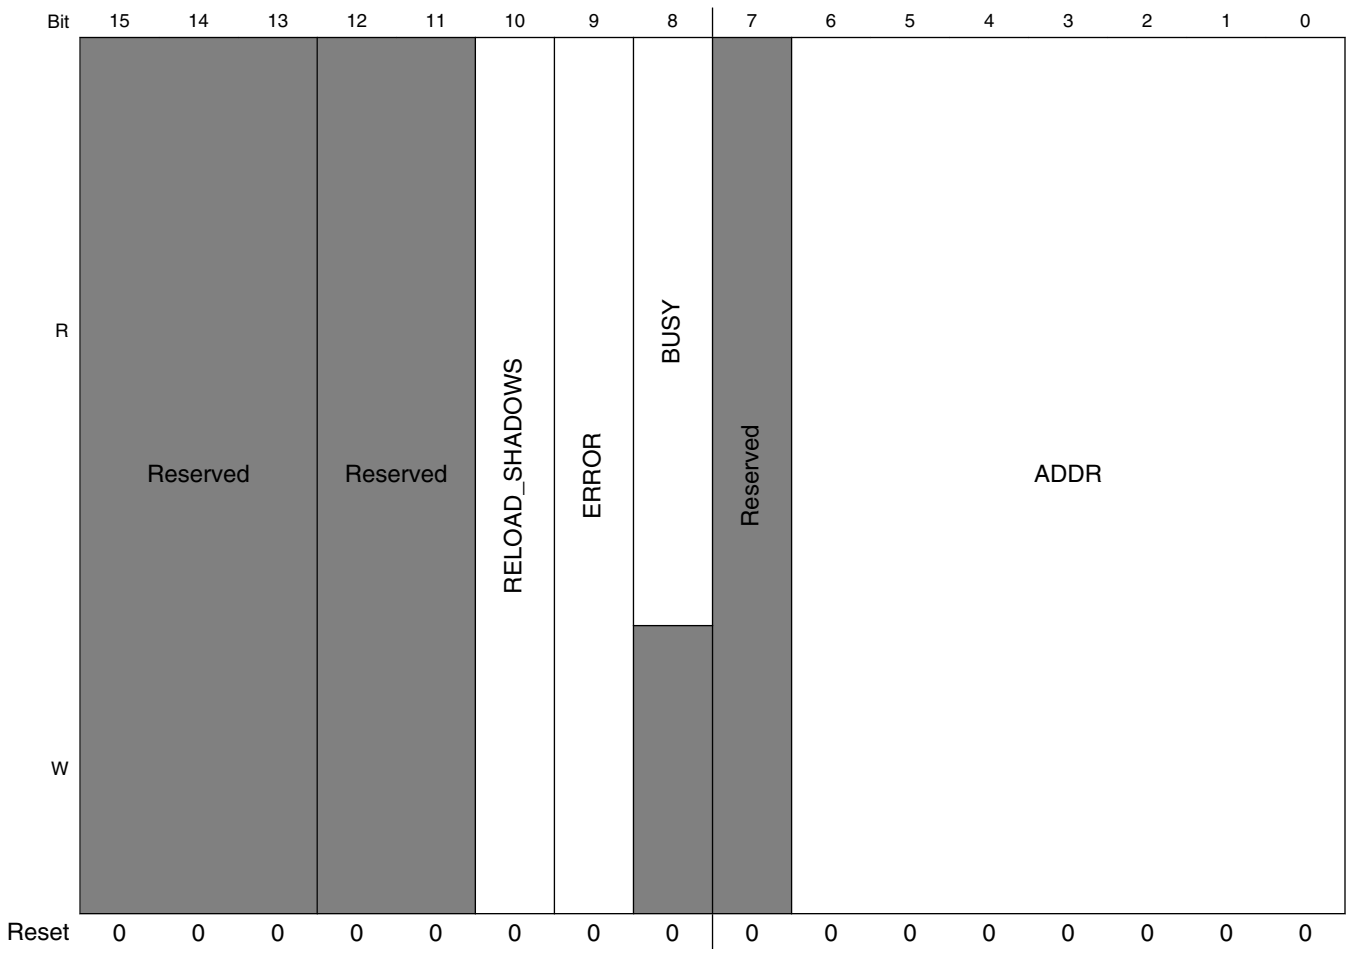
The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjuction with the HW_OCOTP_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and HW_OCOTP_READ_CTRL register. Read value is saved in HW_OCOTP_READ_FUSE_DATA register.

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 0h offset + (4d × i), where i=0d to 3d





OCOTP_CTRL*n* field descriptions

Field	Description
31–16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: This register must be unlocked on a write-by-write basis (a write is initiated when HW_OCOTP_DATA is written), so the UNLOCK bitfield must contain the correct key value during all writes to HW_OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY). 0x3E77 **KEY** — Key needed to unlock HW_OCOTP_DATA register.
15–13 -	This field is reserved. Reserved
12–11 -	This field is reserved. Reserved
10 RELOAD_ SHADOWS	Set to force re-loading the shadow registers (HW/SW capability and LOCK). This operation will automatically set BUSY. Once the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 ERROR	Set by the controller when an access to a locked region(OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface is active and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a one to the SCT clear address space and not by a general write.
8 BUSY	OTP controller status bit. When active, no new write access or read access to OTP(including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7 -	This field is reserved. Reserved
ADDR	OTP write and read access address register. Specifies one of 128 word address locations (0x00 - 0x7f). If a valid access is accepted by the controller, the controller makes an internal copy of this value. This internal copy will not update until the access is complete.

46.5.2 OTP Controller Timing Register (OCOTP_TIMING)

The OCOTP Data Register is used for OTP Programming

This register specifies timing parameters for programming and reading the OCOTP fuse array.

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 10h offset = 21B_C010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				WAIT						STROBE_READ						RELAX				STROBE_PROG											
W																																
Reset	0	0	0	0	0	0	0	1	0	1	0	0	0	1	1	0	0	0	0	1	0	0	1	0	1	0	0	1	1	0	0	1

OCOTP_TIMING field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–22 WAIT	This count value specifies time interval between auto read and write access in one time program. It is given in number of ipg_clk periods.
21–16 STROBE_READ	This count value specifies the strobe period in one time read OTP. Trd = ((STROBE_READ+1)- 2*(RELAX+1)) /ipg_clk_freq. It is given in number of ipg_clk periods.
15–12 RELAX	This count value specifies the time to add to all default timing parameters other than the Tpgm and Trd. It is given in number of ipg_clk periods.
STROBE_PROG	This count value specifies the strobe period in one time write OTP. Tpgm = ((STROBE_PROG+1)-2*(RELAX+1)) /ipg_clk_freq. It is given in number of ipg_clk periods.

46.5.3 OTP Controller Write Data Register (OCOTP_DATA)

The OCOTP Data Register is used for OTP Programming

This register is used in conjuction with HW_OCOTP_CTRL to perform one-time writes to the OTP. Please see the "Software Write Sequence" section for operating details.

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 20h offset = 21B_C020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_DATA field descriptions

Field	Description
DATA	Used to initiate a write to OTP. Please see the "Software Write Sequence" section for operating details.

46.5.4 OTP Controller Write Data Register (OCOTP_READ_CTRL)

The OCOTP Register is used for OTP Read

This register is used in conjuction with HW_OCOTP_CTRL to perform one time read to the OTP. Please see the "Software read Sequence" section for operating details.

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 30h offset = 21B_C030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved															READ_FUSE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_READ_CTRL field descriptions

Field	Description
31–1 -	This field is reserved. Reserved
0 READ_FUSE	Used to initiate a read to OTP. Please see the "Software read Sequence" section for operating details.

46.5.5 OTP Controller Read Data Register (OCOTP_READ_FUSE_DATA)

The OCOTP Data Register is used for OTP Read

The data read from OTP

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 40h offset = 21B_C040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_READ_FUSE_DATA field descriptions

Field	Description
DATA	The data read from OTP

46.5.6 Sticky bit Register (OCOTP_SW_STICKY)

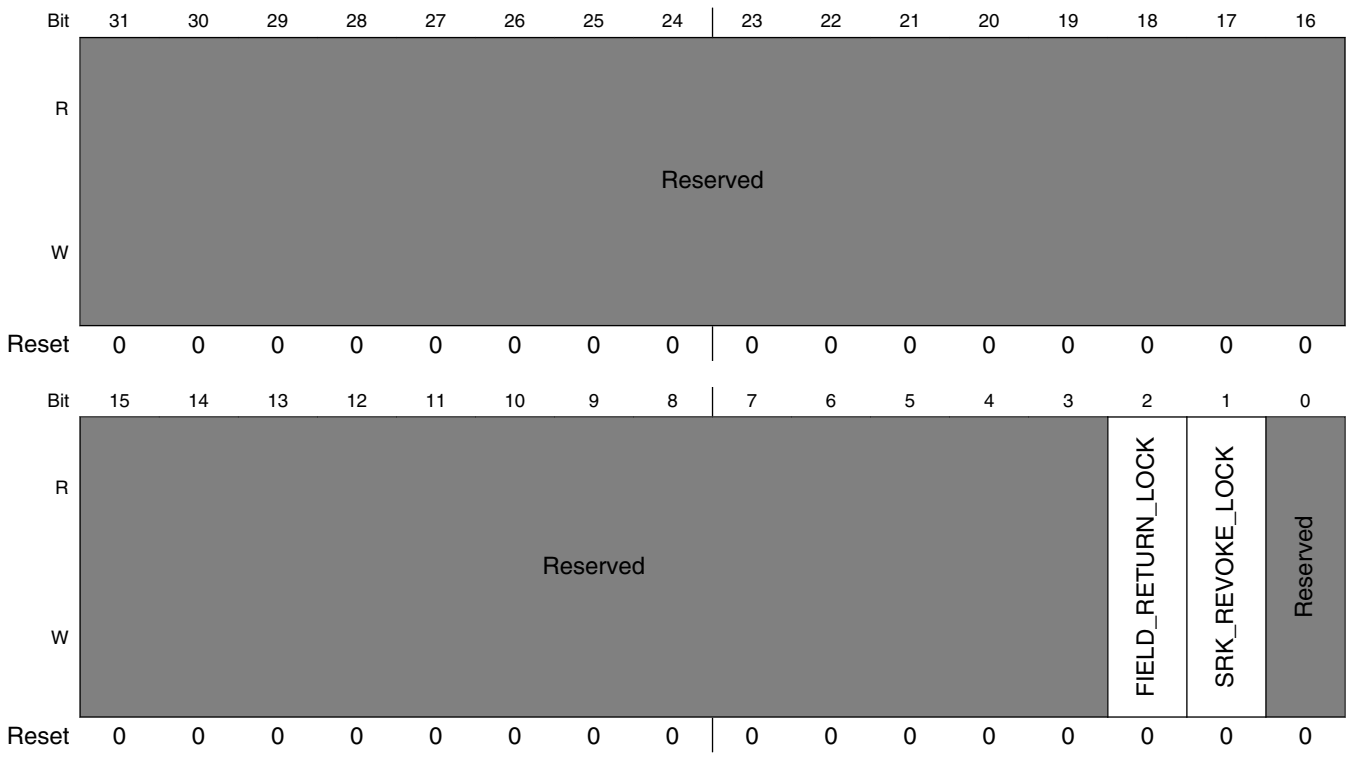
Some SW sticky bits .

Some sticky bits are used by SW to lock some fuse area , shadow registers and other features.

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 50h offset = 21B_C050h



OCOTP_SW_STICKY field descriptions

Field	Description
31–3 -	This field is reserved. Reserved
2 FIELD_ RETURN_LOCK	Shadow register write and OTP write lock for FIELD_RETURN region. When set, the writing of this region's shadow register and OTP fuse word are blocked.Once this bit is set, it is always high unless a POR is issued.
1 SRK_REVOKE_ LOCK	Shadow register write and OTP write lock for SRK_REVOKE, MC_ERA and AP_BI_VER regions. When set, the writing of these region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
0 -	This field is reserved. Reserved.

46.5.7 Software Controllable Signals Register (OCOTP_SCS*n*)

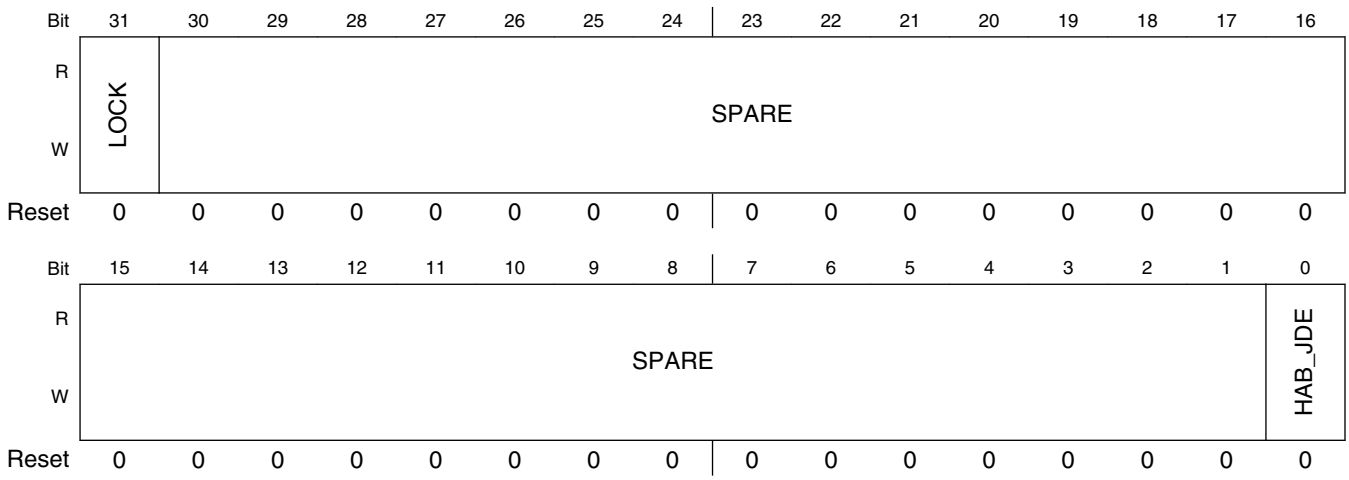
HW_OCOTP_SCS: 0x060

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their defualt values after POR.

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 60h offset + (4d × i), where i=0d to 3d



OCOTP_SCS*n* field descriptions

Field	Description
31 LOCK	When set, all of the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a POR is issued.
30–1 SPARE	Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by POR. 0: JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms). 1: JTAG debugging is enabled by the HAB (though this signal may be gated off). 1 JTAG debugging is enabled by the HAB (though this signal may be gated off)

46.5.8 OTP Controller Version Register (OCOTP_VERSION)

This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 90h offset = 21B_C090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MAJOR								MINOR								STEP															
W																																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

46.5.9 Value of OTP Bank0 Word0 (Lock controls) (OCOTP_LOCK)

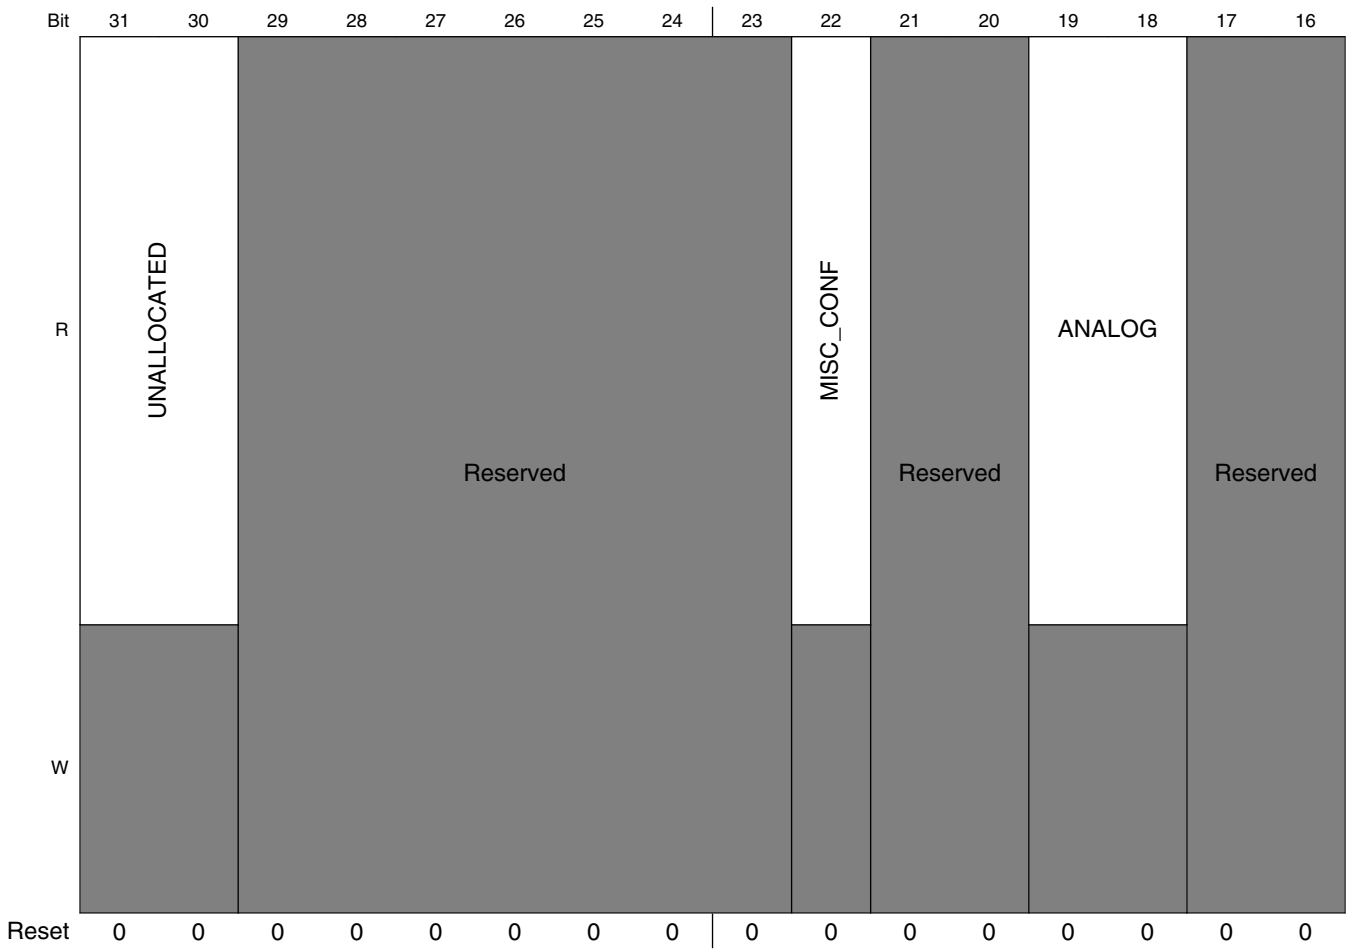
Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

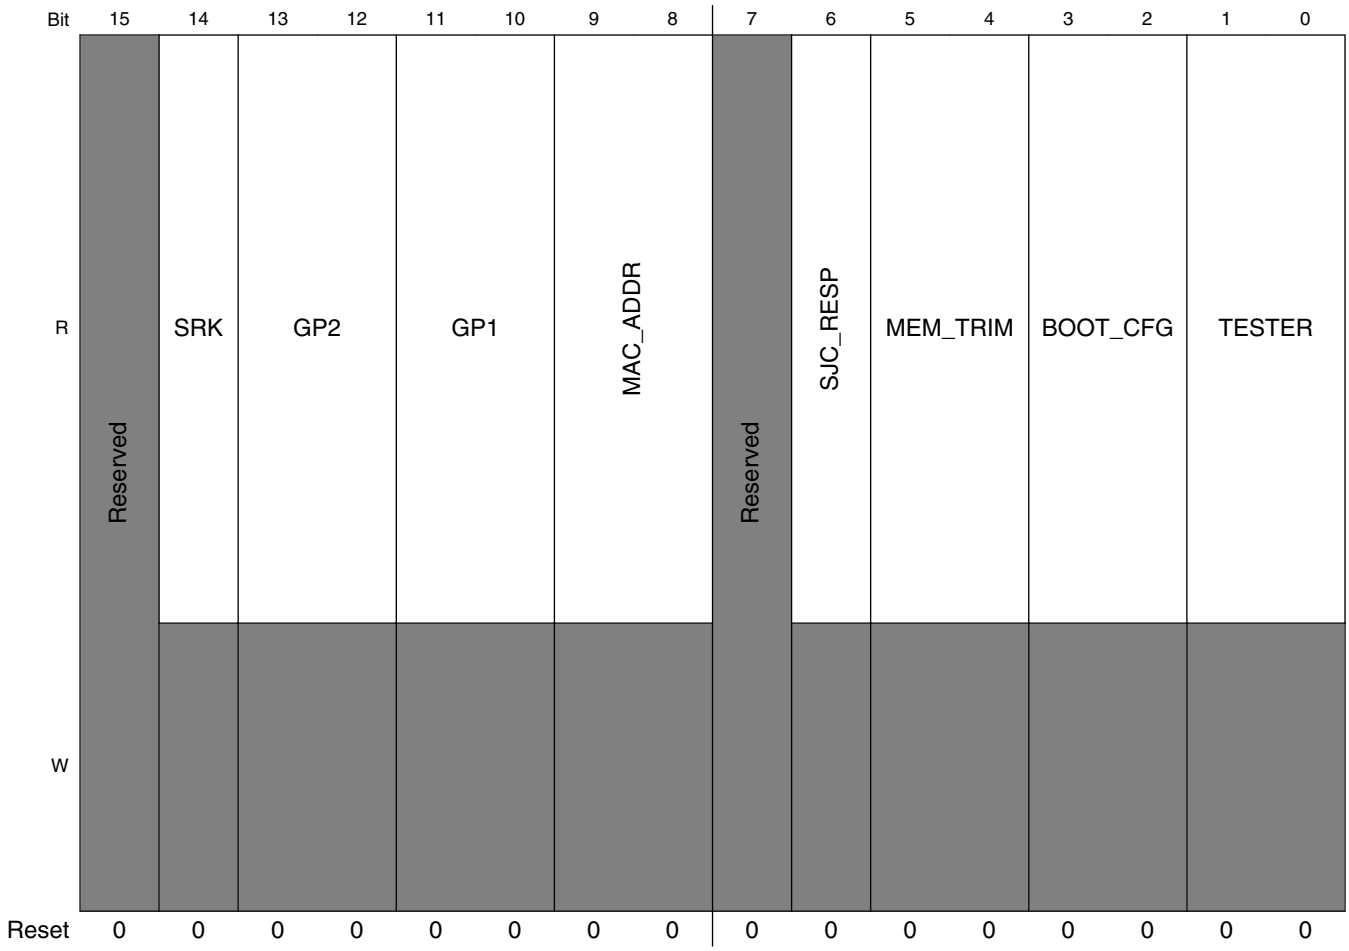
Shadowed memory mapped access to OTP Bank 0, word 0 (ADDR = 0x00).

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 400h offset = 21B_C400h





OCOTP_LOCK field descriptions

Field	Description
31–30 UNALLOCATED	Value of un-used portion of LOCK word
29–23 -	This field is reserved. Reserved
22 MISC_CONF	Status of shadow register and OTP write lock for misc_conf region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
21–20 -	This field is reserved. Reserved
19–18 ANALOG	Status of shadow register and OTP write lock for analog region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
17–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14 SRK	Status of shadow register and OTP write lock for srk region. When set, the writing of this region's shadow register and OTP fuse word are blocked.

Table continues on the next page...

OCOTP_LOCK field descriptions (continued)

Field	Description
13–12 GP2	Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
11–10 GP1	Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
9–8 MAC_ADDR	Status of shadow register and OTP write lock for mac_addr region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
7 -	This field is reserved. Reserved
6 SJC_RESP	Status of shadow register read and write, OTP read and write lock for sjc_resp region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
5–4 MEM_TRIM	Status of shadow register and OTP write lock for mem_trim region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
3–2 BOOT_CFG	Status of shadow register and OTP write lock for boot_cfg region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
TESTER	Status of shadow register and OTP write lock for tester region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

46.5.10 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP_CFG0)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 1 (ADDR = 0x01).

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 410h offset = 21B_C410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

OCOTP_MEM1 field descriptions

Field	Description
BITS	Reflects value of OTP bank 1, word 1 (ADDR = 0x09). These bits become read-only after the HW_OCOTP_LOCK_MEM_TRIM[1] bit is set.

46.5.19 Value of OTP Bank1 Word2 (Memory Related Info.) (OCOTP_MEM2)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

Shadowed memory mapped access to OTP bank 1, word 2 (ADDR = 0x0A).

EXAMPLE

```
Empty Example.
```

Address: 21B_C000h base + 4A0h offset = 21B_C4A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 47
On-Chip RAM Memory Controller (OCRAM)

47.1 Overview

The on-chip RAM is implemented as a slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory block, it has one bank of single port SRAM and supports one AXI port.

For the AXI port, the read and write transactions are handled by two independent blocks. As it is possible to have simultaneous read and write requests from the AXI bus, an arbiter with round-robin scheme is implemented to handle this. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.

Various options are provided for adding pipeline or wait-states in read/write access, in order to ensure flexible timing control at both high and low frequencies.

The internal block diagram is shown in the figure below.

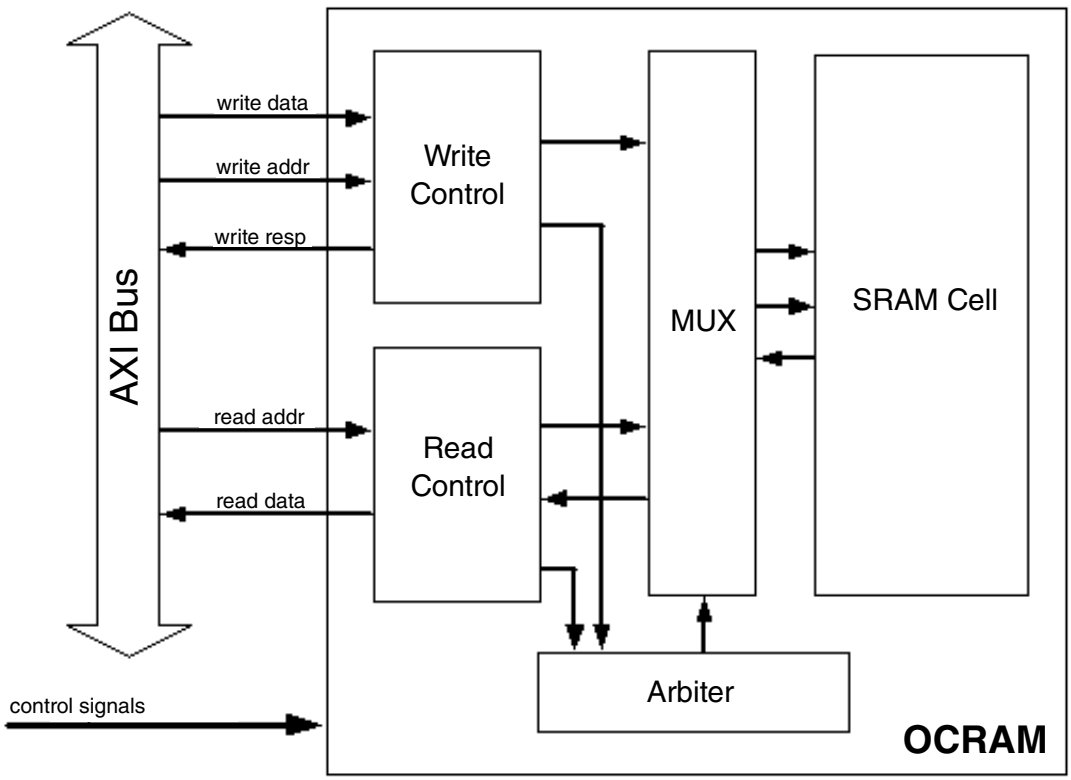

Figure 47-1. On-chip RAM Block Diagram

47.2 Basic Functions

47.2.1 Memory Map

The total on-chip RAM size for i.MX 6Dual/6Quad is 256Kbytes, organized as 16K x 64 bits, mapped from 0x00900000 to 0x0093FFFF.

Memory alias is also supported for on-chip RAM. Address from 0x00940000 to 0x009FFFFF are alias addresses for it, any read/write operation to this area will be mapped back to the 256 Kbytes area.

The 32-bit AXI address are arranged as shown in the table below.

Table 47-1. On-Chip RAM Address Bits

AHB ADDR Bits	Usage	Description
29:3	Address	Selects one of the 16 K words in the memory(64-bit a word).
2:0	Byte Address	Selects/masks out specific bytes within a word.

47.2.2 Read/Write Arbitration

The read/write arbitration uses the round-robin method.

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

47.3 Advanced Features

This section describes some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

All of the features can be disabled/enabled by programming the corresponding fields of the General Purpose Regsiter (IOMUXC.GPR3) bits [24:21] in the IOMUX chapter.

47.3.1 Read Data Wait State

When the wait state is enabled, it will cost 2 cycles for each read access, (each beat of a read burst).

This can avoid the potential timing problem caused by the relatively longer memory access time at higher frequency.

When this feature is disabled, it only costs 1 clock cycle to finish a read transaction, that is, to get read data back in the next cycle of read request becomes valid on the bus.

The read data wait state is configurable via IOMUXC.GPR3[21].

47.3.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

The read address pipeline is configurable via IOMUXC.GPR3[22].

47.3.3 Write Data Pipeline

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

The write data pipeline is configurable via IOMUXC.GPR3[23].

47.3.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

The write address pipeline is configurable via IOMUXC.GPR3[24].

47.4 Programmable Registers

There are no programmable registers in this block; however, OCRAM configurable bits can be found in the IOMUX Controller (IOMUXC) general purpose registers found here.

- TrustZone bits: IOMUXC_GPR10
- WAIT state / Pipeline bits: IOMUXC_GPR3
- L2 Cache OCRAM enable bits: IOMUXC_GPR11

(See IOMUXC Memory Map/Register Definition for more details).

Chapter 48
PCI Express (PCIe)

48.1 Overview

PCI Express includes the following cores:

- PCI Express Dual Mode (DM) core
- PCI Express Root Complex (RC) core
- PCI Express Endpoint (EP) core

NOTE

Throughout this chapter, content that is specific to a core is identified by using the abbreviated core name; for example, DM, RC, EP. Content that applies to the DM core specifically in either RC mode or EP mode is further qualified by using RC Mode or EP Mode. Content that applies to all cores is not identified as being specific to any core; rather, the term core or cores is used.

48.1.1 Terms and Abbreviations

The following terms are used throughout this chapter:

Table 48-1. Terms and Abbreviations

Term	Description
DM	PCI Express Dual Mode (DM) core
RC	PCI Express Root Complex (RC) core
EP	PCI Express Endpoint (EP) core
PCIe	PCI Express
CXPL	Common Xpress Port Logic: An internal Port Logic core module that implements the majority of the PCI Express protocol
x1/x2/x4/x8/x16	1/2/4/8/16 lanes

Table continues on the next page...

Table 48-1. Terms and Abbreviations (continued)

PIPE	PHY Interface for the PCI Express Architecture
NW	Number of double words; 1 stands for a 32-bit DWORD
DW	Data width: 32, 64, or 128 bits
NF	Number of functions; 1 stands for one function
TLP	Transaction Layer Packet
DLLP	Data Link Layer Packet
VC	Virtual Channel
BAR	Base Address Register
XADM	Transmit application-dependent module.
RADM	Receive application-dependent module.
PMC	Power management controller.
RAMI	External RAM interface.
Core	Identifies the entire core. The core includes the native PCIe-core and AXI/AHB bridge if present.
Native PCIe core	Identifies the basic PCIe core which has its own non-standard, proprietary dedicated bus interface to the application.
CDM	Configuration Dependent Module This is an internal block in the native core that houses the PCI configuration registers and some user-accessible registers that reside in the core. In general, an application may use our core, but will add other registers that are unique to their applications. Those new application registers will be referred to as External Application Registers (EAR).
LBC	Local Bus Controller This is an internal block that resides in the native core. It allows the DBI interface (from the application side) or the wire side interface (via the radm_TRGT0 interface) to access the core's Configuration Dependent Module (CDM) registers and/or the External Application Registers (EAR). (For additional details on this module, please refer to the native core documentation.)
ELBI	External Local Bus Interface This is an interface on the native core that processes read/write access to the external application registers (EAR). For applications that require external registers, the application can access the EAR through the bridge or an entirely different interface (outside the scope of this core). (For additional details on this interface, please refer to the native core's documentation.)
DBI	Data Bus Interface This bus is internal to the native core. This interface is used to access the core's internal registers (CDM) or the external application's device-specific registers attached to the PCIe native core ELBI interface.
VMI	Vendor Message Interface.
Inbound traffic	PCIe transactions that enter the native core from the wire side of the core (PCIe wire). These transactions will be delivered to the application side.
Outbound traffic	Transactions that enter the native core from the application side of the core. These are passed to the native core, where they will be sent out onto the PCIe wire.
MTU	Maximum Transfer Unit Specifies the maximum packet payload size supported. This indicates the maximum allowed transfer size for a write or completion.
Page boundary	Specifies the address page boundary size supported by the bridge. No packet can have an address that crosses the specified address boundary.
big-endian	Data format in which most significant byte comes first; normal order of bytes in a word.

Table continues on the next page...

Table 48-1. Terms and Abbreviations (continued)

RBYP	Receive Bypass Interface
RTRGT1	Receive Target 1 Interface
RCPL	Receive Completion Interface
XALI0/1/2	Transmit Application Client Interfaces
SII	System Information Interface.
iATU	Internal Address Translation Unit.

48.2 Architecture

This information describes the architecture of the PCI Express core.

The topics for this section are:

- Common Xpress Port Logic (CXPL)
- Transmit Application-Dependent Module (XADM)
- Receive Application-Dependent Module (RADM)
- Configuration-Dependent Module (CDM)
- Power Management Controller (PMC)
- Local Bus Controller (LBC) and Data bus Interface (DBI)
- Message Generation
- Debug and Diagnostics

The Common Xpress Port Logic (CXPL) module implements the basic functionality for the PCI Express Physical, Link, and Transaction Layers. In addition to the CXPL, there are several top-level modules that provide the configurationim and mode- specific features:

- Transmit Application-Dependent Module (XADM)
- Receive Application-Dependent Module (RADM)
- Configuration-Dependent Module (CDM)
- Power Management Controller (PMC)
- Local Bus Controller (LBC) and Data bus Interface (DBI)
- Message Generation

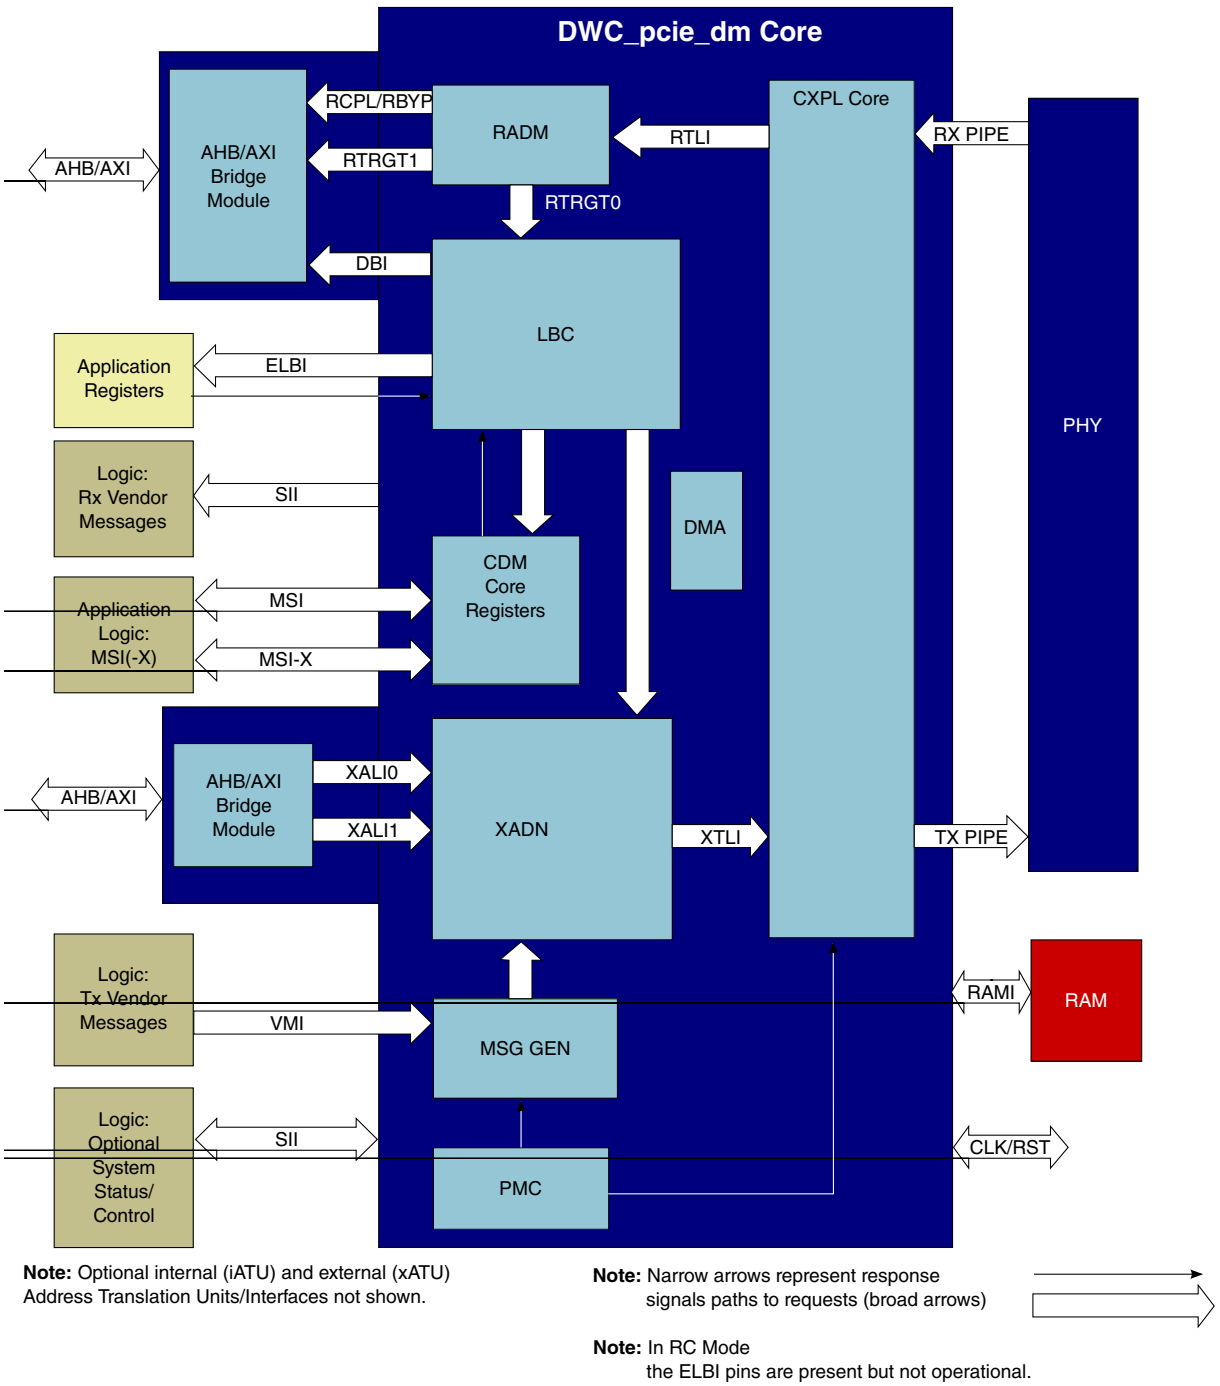

Figure 48-1. DM Core Block Diagram (with AXI Bridge Module)

NOTE

- Optional internal (iATU) and external (xATU) Address Translation Units/Interfaces not shown.
- Narrow arrows represent response signal paths to requests (broad arrows)
- In RC mode the ELBI pins are present but not operational.

For definitions of acronyms used for block and interface names, see Terms and Abbreviations.

Table 48-2. Core Interface Summary

Interface	Function
Transmit Client 0 Interface (XALI0)	Transmit interface for outbound Request or Completion TLPs.
Transmit Client 1 Interface (XALI1)	Additional application transmit interface, identical to XALI0. The usage of XALI0 and XALI1 is up to the application. For example, an application may use XALI0 for Requests and XALI1 for Completions.
Receive Completion Interface (RCPL)/Bypass Interface (RBYP)	When the core is configured in single or multiple queue architecture, RCPL delivers Completions received by the core to the application client that requested them. When the core is configured in segmented buffer queue mode, Bypass delivers all transactions that are configured as bypass.
Receive Target 1 Interface (RTRGT1)	Delivers inbound Requests received by the core after the Requests are qualified by the filter rules of the core.
Data Bus Interface (DBI)	Delivers an RD/WR request from application logic such as EEPROM to internal registers of the core or application registers at ELBI.
Message Signaled Interrupt (MSI) Interface	Allows the application to request a transmission of an MSI independent from the client interfaces. MSI interface is used only in EP mode.
MSI-X Interface	Allows the application to request a transmission of an MSI-X independent from the client interfaces. MSI-X interface is used only in EP mode.
Vendor Message Interface (VMI)	Allows the application to request a transmission of a vendor message independent from the client interfaces.
System Information Interface (SII)	Exchanges system information between the core and the application.
PIPE	Standard PIPE interface between the PCI Express PHY and the core.
RAM Interface (RAMI)	Optional top-level interface to connect external RAMs for the retry buffer and receive queues. If you do not select the optional top-level RAMI, the RAMs reside inside the top-level hierarchy of the core.

48.2.1 Common Xpress Port Logic (CXPL)

The CXPL module implements a large portion of the Transaction Layer logic, all of the Data Link Layer logic, and the MAC portion of the Physical Layer, including the Link Training and Status State Machine (LTSSM).

The CXPL connects to the external PHY though the PIPE.

Important aspects of the CXPL and overall core implementation include:

- Layer 3 (Transaction Layer) functionality is split between the XADM, RADM, CDM, and CXPL.

- Layer 1(Physical Layer) is split across the PIPE such that the MAC functionality is in the core and the PHY functionality is implemented in the PIPE-compliant PHY.the PHYmodule resides outside of the core, interfacing through the standard PIPE.
- Receive and transmit path functionality is decoupled except where communication between the two is required (such as Flow Control and other low-level Link management functions).

CXPL contains six modules, three for transmission and three for reception, as shown in the figure below.

- RTLH: Receive Transaction Layer Handler
- XTLH: Transmit Transaction Layer Handler
- RDLH: Receive Data Link Layer Handler
- XDLH: Transmit Data Link Layer Handler
- RMLH: Receive MAC Layer Handler
- XMLH: Transmit MAC Layer Handler

CXPL is compliant with the PCI Express 3.0 Specification with regards to the physical layer, data link layer and transaction layer.

1. PCS soft logic and timing model for mixed signal PMA

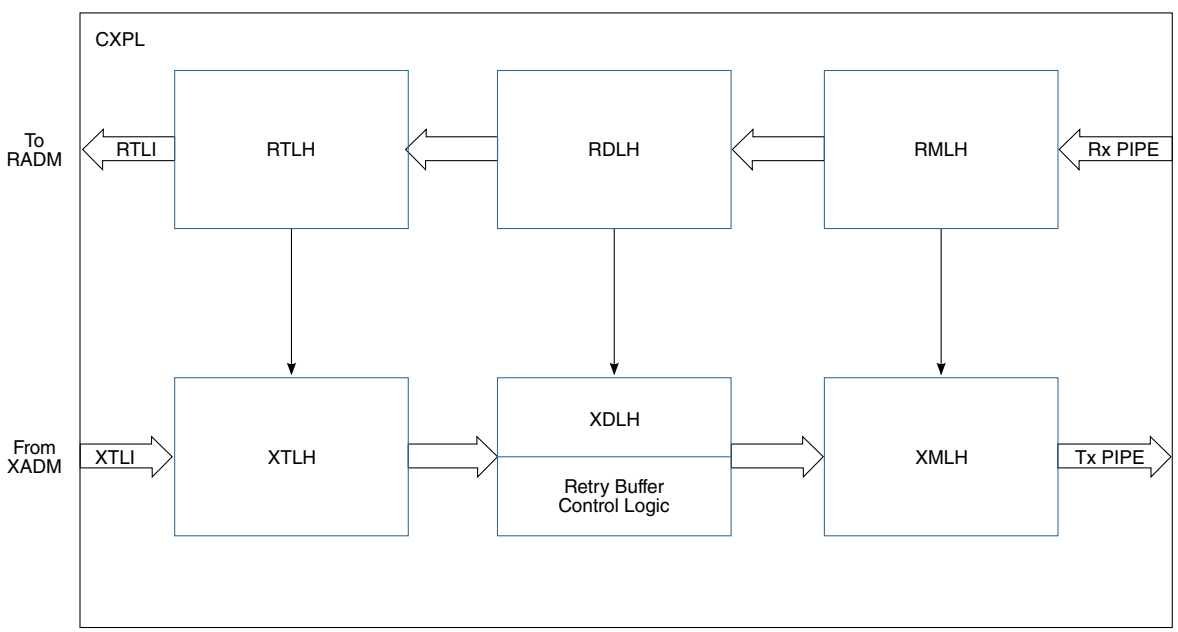

Figure 48-2. CXPL Module Block Diagram

48.2.2 Transmit Application-Dependent Module (XADM)

The XADM sits between the application logic and the CXPL core and implements the mode-specific functionality of the PCI Express Transaction Layer for packet transmission.

The figure below is a block diagram of the XADM. Its functions include arbitration, TLP formation, and credit checking.

The transmit path uses a cut-through architecture. It does not implement transmit buffering/queues (other than the retry buffer). Depending on system design, an externally-implemented transmit queue can be used to handle rate matching if the CXPL and application transfer rates are different. For relevant information on this in the context of using the AHB/ AXI Bridge as an application to the XADM.

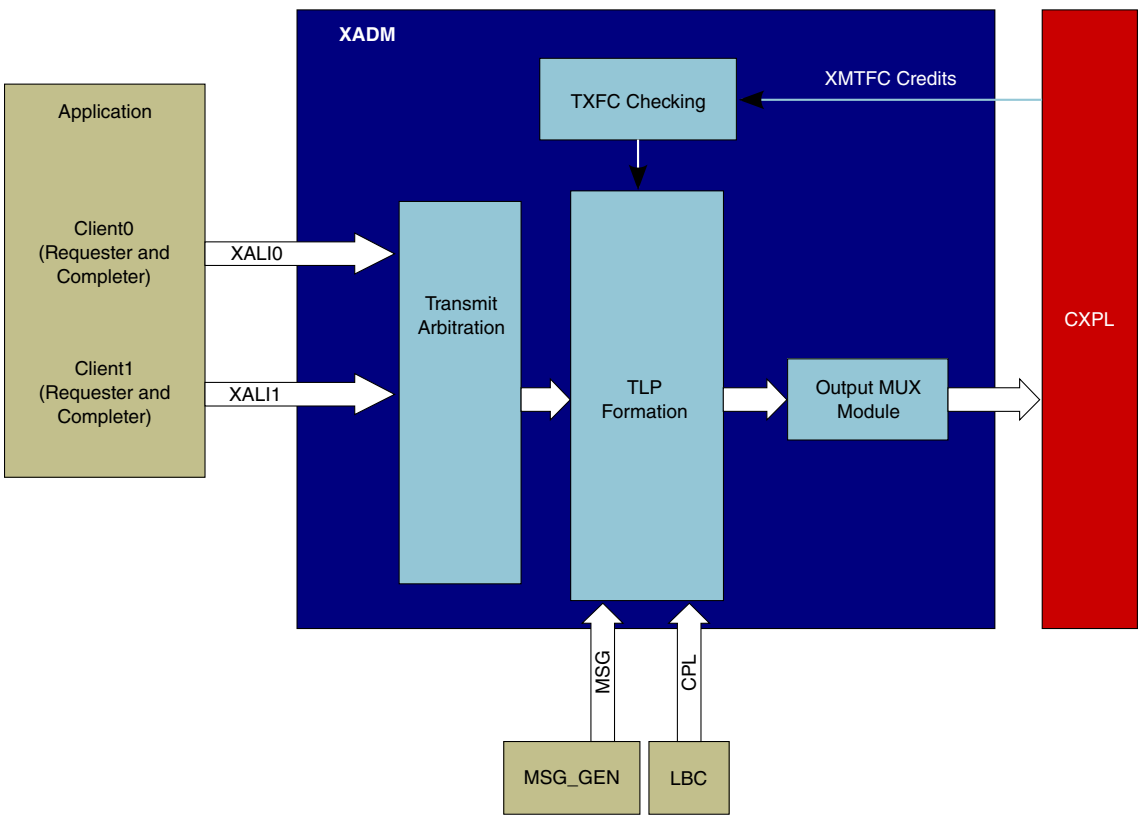

Figure 48-3. XADM Block Diagram

48.2.2.1 Arbitration

XADM provides the arbitration of TLP transmission between the following:

- The transmit client interfaces (XALI0, XALI1)
- Internally generated Messages from the MSG_GEN, triggered by PME, INTx (EP mode), errors, or application logic
- Internally generated Completions:
- EP mode: Internally generated Completions are responses for type 0 Configuration Read and Write Requests from upstream components, memory or I/O-mapped application register space Read and Write Requests, or responses to error conditions (Unsupported Requests).
- RC mode: Internally generated Completions are Unsupported Request or Completer Abort, as required by the incoming Request filtering function of the RADM.

In general, all internally generated TLP requests have higher priority than client interfaces.

For details about how the arbitration methods work and how to configure the arbitration methods, see Transmit TLP Arbitration.

48.2.2.2 Credit Checking

The core checks that enough FC credits are available in the remote device for the specific type of transaction (P, NP, CPL) before allowing a transmission of a TLP. TLPs that passed the credit check are arbitrated according to the supported arbitration method. Internally generated Completions and Messages are also gated by the arbitration logic, though at highest priority, and must also pass the FC credit test before they are accepted for transmission.

48.2.3 Receive Application-Dependent Module (RADM)

The RADM sits between the application logic and the CXPL core and implements the mode-specific functionality of the PCI Express Transaction Layer for TLP packet reception.

The figure below shows a block diagram of the RADM. The RADM serves four major functionalities as following:

- Sort/Filter received TLPs
- Completion Lookup Table (CLT), which is used for Completion tracking and Completion timeout monitoring of transmitted Non-Posted requests.
- Provide queuing (or bypass) of the received TLP
- Output received TLP to the core's receive interface (Demux function)

The filtering rules and routing for all TLP receive options are configurable for all TLPs received.

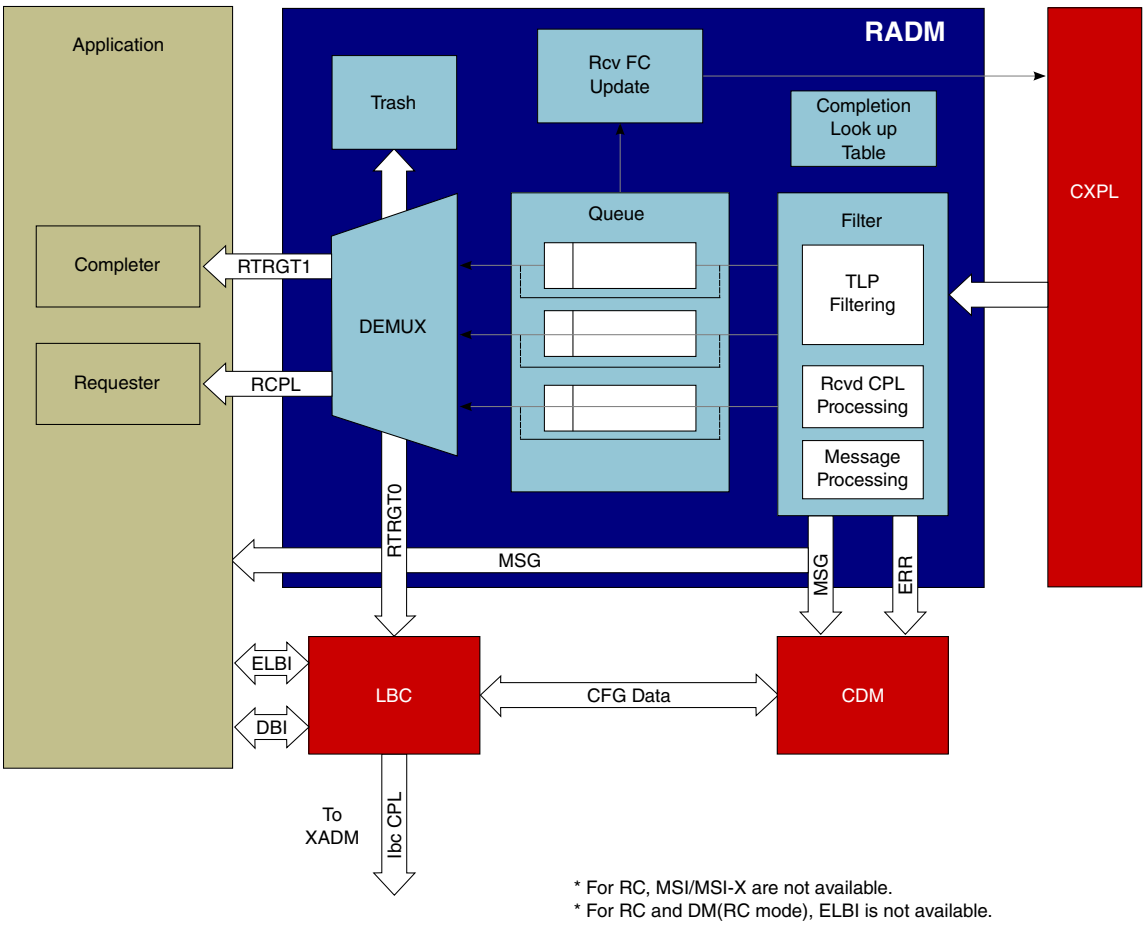

Figure 48-4. RADM Block Diagram

48.2.3.1 Posted and Non-Posted Request and Completion TLP Processing

The RADM filter passes the Posted and Non-Posted Request and Completion transactions (such as Write Transactions and Memory Reads) directly to the application through the RTRGT1 interface or to RTRGT0 for internal modules, as determined by the filtering and routing rules for the current operating mode, as described in Receive Filtering.

The RADM filter segregates Posted and Non-Posted TLPs into valid supported and valid un-supported Requests, and forwards them to the queue. The filter processes each Request and determines each TLP's destination along with other controls that may be needed to generate TLPs.

For Requests that the core forwards to the RTRGT1 or Bypass interface, the application must process the Request and generate the Completion.

For Requests that the core forwards to RTRGT0, the core automatically generates the Completion. The core automatically executes any required ELBI access before generating the Completion.

48.2.3.1.1 TLP Routing

The RADM demux is designed to mux out a received TLP to the RTRGT1 and RCPL/RBYP interfaces from single queue or multiple queue (DM/RC/EP) configurations. The filter determines the destination and the action for each TLP, then sends this to the queue. The demux decides whether to discard or forward the TLP onto the RTRGT1, RTRGT0, RCPL or RBYP interfaces.

For more details see Receive Routing and Queue to Port Mapping.

48.2.3.2 Received Completion TLP Processing

Received Completions are filtered against the completion lookup table content before presenting the Completion to the queue.

The RADM also implements a Completion time-out mechanism (via the Completion Lookup Table) and notifies the application when an expected Completion-corresponding to a transmitted Non Posted TLP-does not arrive within a specified time.

The Completion Lookup Table (and Completion Timeout event) should not be confused with the Target Completion Lookup table (and Target Completion Timeout event) .

The Target Completion Lookup Table is watching for received application completions (on XALI0/1) corresponding to previously received Non Posted requests.

The Completion Lookup Table is watching for received PCIe completions corresponding to previously transmitted Non Posted requests.

Typically, infinite Completion credits are advertised and the received completion is configured in bypass mode which means that there is no queue in the core to store completions.

NOTE

It is fully expected that the application will have enough buffering space ready for its requests, so no backpressure mechanism is needed. By default, the Completion queue operates in bypass mode.

Completions can be configured in store and forward mode if the application has chosen to do so. If a completion lookup has failed or other completion filtering has failed, the core will assert an abort signal at the end of the transaction. If the core is configured to have Completions in bypass mode, it is the application's responsibility to roll back any actions at the application's queue when an abort signal is asserted. If the core is configured with Completions enqueued, the Completion will be discarded by the core and flow control credits will be updated, as necessary, when an abort signal is detected.

48.2.3.3 Message Processing

The RADM filter provides a Message interface (grouped as part of the SII) to handle the Message TLPs received from the upstream component. The RADM filter processes the Message and decodes the header before sending it to the application logic on the SII. You can also select a configuration option to send the entire Message TLP to the application in addition to providing the decoded Message on the SII. For more details see Message Reception.

48.2.4 Configuration-Dependent Module (CDM)

The CDM implements the standard PCI Express configuration space and the core-specific register space. The CDM also requests the Message generation module to send Messages, as required, including MSI and interrupts.

The specific PCI Express configuration structures implemented in the CDM include the following:

PCI-Compatible Configuration Registers

- RC mode: Type 1 header
- EP mode: Type 0 header

PCI Capability Structures:

- PCI Power Management Capability Structure
- MSI Capability Structure

- MSI-X Capability Structure
- VPD (Vital Product Data) Capability

PCI Express Capability Structure

PCI Express Extended Capabilities:

- Advanced Error Reporting Capability
- Virtual Channel Capability
- Device Serial Number Capability
- Power Budgeting Extended Capability

The configured device type (determined by the device_type[3:0] input signal) affects the behavior of the Message generation engine, error reporting mechanism, as well as some PCI Express configuration space registers.

The CDM communicates with application's host bus controller through the DBI. The host bus controller controls accesses to registers within each CDM in multiple instances of the core in a multi-port design.

48.2.5 Local Bus Controller (LBC) and Data bus Interface (DBI)

This following topics are covered in this section:

- Overview (LBC)
- ELBI
- CDM Register Space Layout
- PCI Configuration Header and Capability Registers (in CDM)
- Port Logic (PL) Registers (in CDM)
- PCIe Wire Access (EP mode)
- PCIe Wire Access (RC mode)
- DBI Access
- LBC/DBI Feature Availability
- LBC/DBI Size Limitations
- AXI DBI Limitations

48.2.5.1 Overview (LBC)

The LBC module provides a mechanism for a link partner PCIe device (in EP mode only) or a local CPU (through the DBI) to access internal registers (in the CDM) .

NOTE

In RC mode:

The application can access CDM registers through the DBI.

PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

Figure 48-5 shows the location of the LBC within the PCIe core and its role in routing transactions.

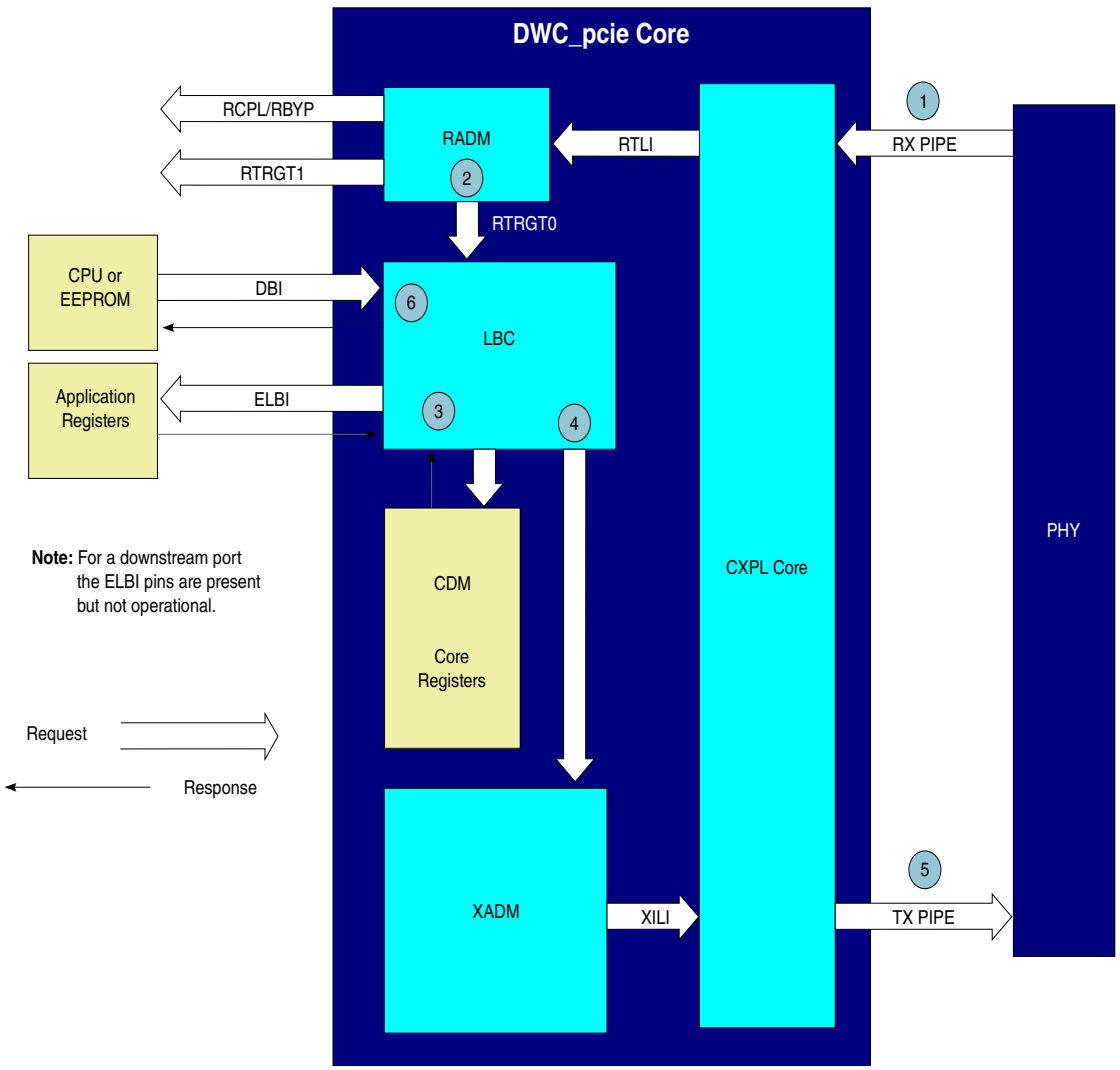

Figure 48-5. LBC Context

The LBC provides a Switched access function to internal registers (in the CDM)from the local application processor (CPU) via the DBI or the remote application software (off the PCIe RX wire) via RTRGT0. Figure 48-6 illustrates the four possible request paths through the LBC.

For more information on the filtering and routing of received inbound TLPs, see Receive Routing.

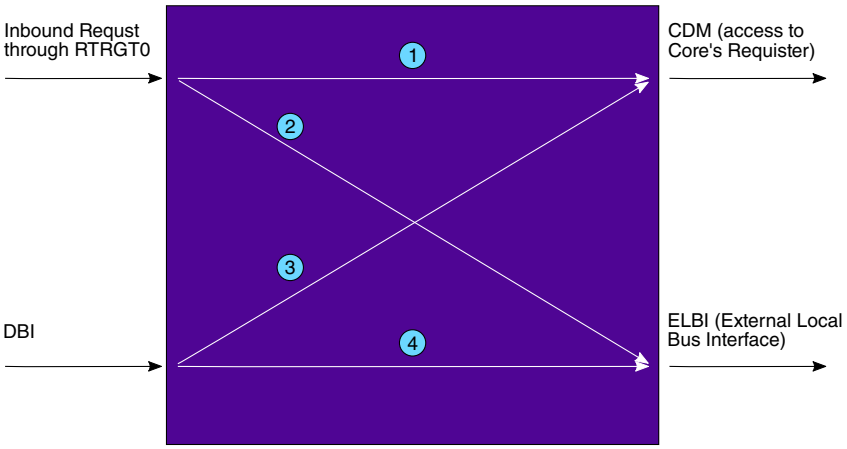

Figure 48-6. LBC Switch

NOTE

In RC mode PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

48.2.5.1.1 Simultaneous Transactions

The LBC is single-threaded and therefore, the DBI and RTRGT0 cannot use the LBC at the same time. For example, a request on the DBI will not be accepted, during a RTRGT0 transaction, until both parts of that transaction - [1] request and [2] response (completion generation) - are completed.

If the DBI and RTRGT0 present a request at the same time (regardless of the target/destination of each request), then the LBC will grant access to the RTRGT0.

48.2.5.2 ELBI

You can connect external application registers to the ELBI. These can be accessed by PCIe request TLPs over the PCIe link or by the DBI.

NOTE

In RC mode PCIe wire access (through RTRGT0) to the ELBI is NOT possible.

48.2.5.3 CDM Register Space Layout

The core has 4096 bytes of PCI Express configuration space per function distributed as per the figure below. This address space is fully accessible from the DBI without any restrictions.

In EP mode it can be accessed from the PCIe wire using CFG requests. Under certain configurations, the Port Logic and ELBI Register spaces can also be accessed from the PCIe wire with MEM and IO requests.

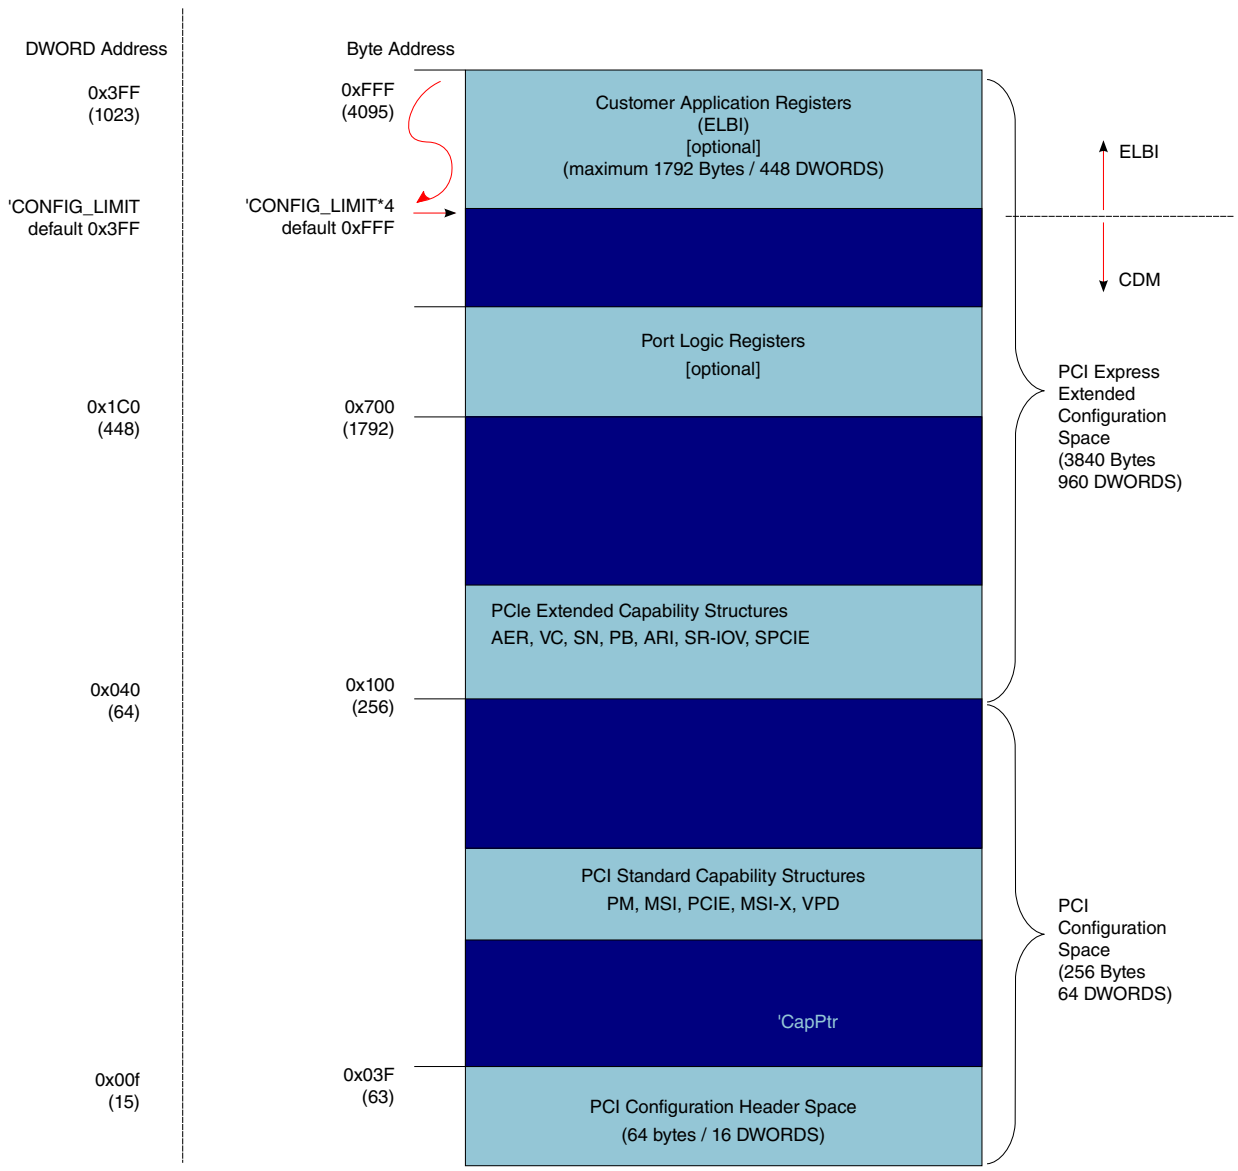

Figure 48-7. PCIe Core Configuration Space Address Map (per function)

A CFG TLP has a 6-bit Register Number Field and a 4-bit Extended Register Number field allowing 1024 DWORDS (4096 bytes) to be accessed.

48.2.5.3.1 PCI Configuration Header and Capability Registers (in CDM)

The PCI Configuration Header and Capability Registers in Figure 48-7 are PCIe core configuration registers specified by the PCI Express 3.0 Specification. Access from the PCIe wire is possible with CFG requests (in EP mode only).

These registers are fully accessible from the DBI without any restrictions.

NOTE

From the PCIe wire (through RTRGT0) in EP mode only:

You can Memory-Map the Port Logic (PL) Register Space.

You cannot Memory-Map the PCI and PCIe Configuration Register Spaces. You must always access them with a CFG request.

NOTE

In RC mode:

PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

NOTE

From the DBI:

You can access without any restriction the Port Logic (PL) Register Space.

You can access without any restriction the PCI and PCIe Configuration Register Spaces.

48.2.5.3.2 Port Logic (PL) Registers (in CDM)

The Port Logic Registers in Figure 48-7 are PCIe core configuration registers not specified by the PCI Express 3.0 Specification, but are specific to the configuration and operation of the PCIe IP core.

In EP mode, access from the PCIe wire is with CFG requests. There is no access from the PCIe wire in RC mode.These registers are fully accessible from the DBI without any restrictions.

48.2.5.3.3 Memory Mapping PL Registers

Port Logic Registers (which by default are accessed by CFG requests) can also (at the same time) be accessed by MEM requests through the use of the ENABLE_MEM_MAP_PL_REG, PL_FUNC_NUM and PL_BAR_NUM configuration parameters. These can be used to map the Port Logic Registers to any BAR of any function.

All MEM requests that match PL_BAR_NUM (when ENABLE_MEM_MAP_PL_REG=1) and whose address offset is in the range 0x700-0x8FF will be routed to the Port Logic Registers.

NOTE

The BAR corresponding to PL_BAR_NUM must also be mapped/assigned to RTRGT0.

48.2.5.4 PCIe Wire Access (EP mode)

By default[1], CFG requests are routed to RTRGT0 and then to CDM via LBC.

By default, BAR-matched MEM/IO requests are routed to RTRGT1.

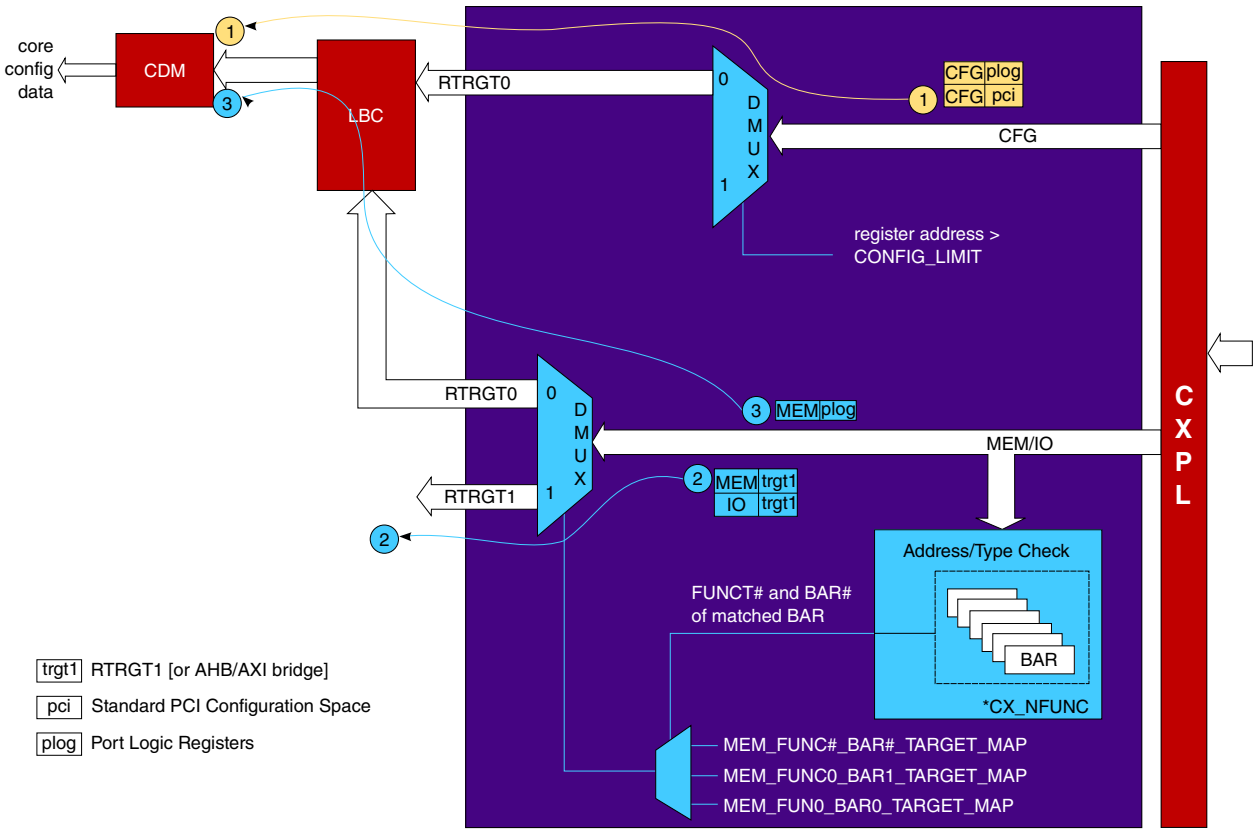

Figure 48-8. Request TLP Routing - Typical Use Model

Looking in detail at the typical routing of inbound PCIe requests (the numbers refer to the paths identified by the circled numbers in the above diagram.

CFG requests-either to Standard PCI Configuration Space or Port Logic Registers-are always routed to the CDM. This is because CONFIG_LIMIT by default is set to 0x3FF (top of the CFG register address space).

BAR-matched MEM/IO requests are routed to RTRGT1. MEM_FUNC#_BAR#_TARGET_MAP for each enabled BAR is set by default to RTRGT1.

Port Logic Registers (which by default are accessed by CFG requests-see [1] above) can also be accessed by MEM requests through the use of the ENABLE_MEM_MAP_PL_REG, PL_FUNC_NUM and PL_BAR_NUM configuration parameters. These can be used to map the Port Logic Registers to any BAR.

To see all routing possibilities, refer to Receive Routing.

48.2.5.5 PCIe Wire Access (RC mode)

To see all routing possibilities, see Receive Routing.

NOTE

In RC mode the application can access CDM registers through the DBI.

PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

48.3 Core Operations

This section describes the operations of the PCI Express core.

48.3.1 Initialization

Immediately after reset the DM core goes into either EP mode or RC mode depending on the state of the device_type input.

The internal configuration registers in the CDM assume their default reset values as listed in the following sections:

- PCIe Registers (EP mode)
- PCIe Registers (RC mode)
- PCIe Registers: Port Logic

The application must keep the app_ltssm_enable signal deasserted after reset until the application is ready to establish a Link and start receiving and transmitting TLPs. If the application needs to update configuration registers in the CDM as part of the initialization process, then the application must keep app_ltssm_enable deasserted until it has programmed all the necessary configuration registers through the DBI.

After initializing the necessary configuration registers, the application can assert app_ltssm_enable to allow the LTSSM to begin Link establishment. The LTSSM begins Link negotiation after the core_rst_n and phy_mac_phystatus signals are deasserted and app_ltssm_enable is asserted.

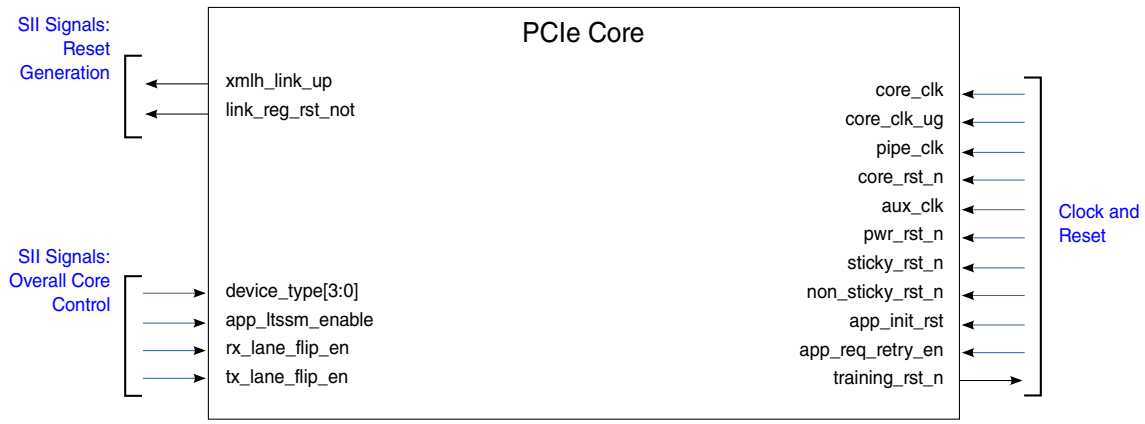

Figure 48-9. I/O Interfaces involved in Initialization

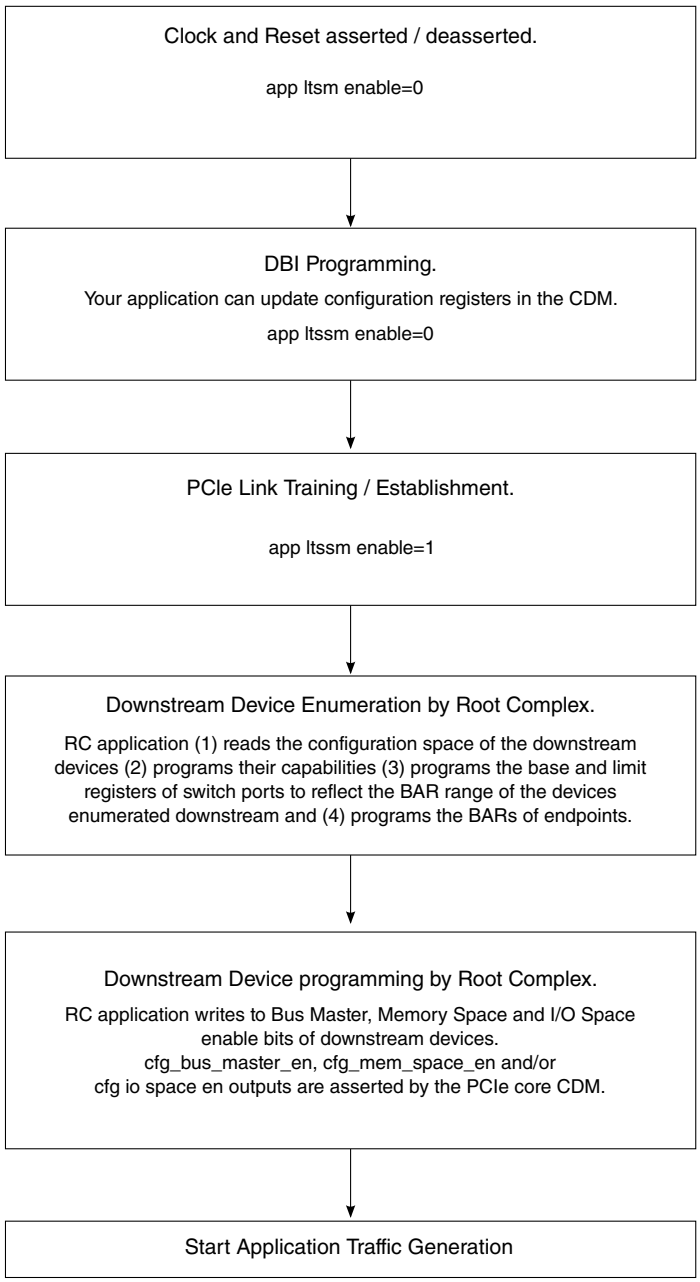

Figure 48-10. PCI Express Initialization Steps

48.3.2 Link Establishment

The core and a PCI Express compliant PHY combine to provide a complete solution for setting up and maintaining a compliant PCI Express Link.

The core implements the LTSSM function according to the *PCI Express 3.0 specification*.

In general, the process for establishing a Link is a follows:

1. Upon power-up (or directly out of reset), it is assumed that the power supply becomes stable and the PLLs reach frequency lock before the devices attempt to establish a valid Link. Once in a valid state, the SerDes either communicates a ready status to the core or simply begins transmitting and receiving valid data.
2. Per the *PCI Express 3.0 specification*, once bit and symbol synchronization are complete, the core initiates the following sequence to establish a Link (assuming a valid and properly functioning Link partner):

Receiver detection on available Lanes for the Port.

Exchange of Training Sequences to determine Link configuration (for example, Link speed, number of Lanes, and order).

Once both partners reach a valid negotiated state, the Link state is set up and the LTSSM is in L0.

1. Once Link up is achieved, the data link modules take over to manage the Link and initialize Flow Control.
2. After Flow Control initialization is complete, the data link modules signal the transaction layer modules that the link is ready to allow transmission/reception of TLP traffic.
3. During normal operation, the LTSSM and data link modules continue to manage the underlying Link integrity while data traffic is communicated across the PCI Express Link.

NOTE

The power management implementation also affects Link establishment.

48.3.3 Transmit TLP Processing

Information found here describes the flow of transmit TLPs through the core.

The topics for this section are:

- Transmit Overview
- Transmit TLP Arbitration
- Transmit Retry
- Transmit DLLP Priorities

It may helpful to first review the following sections: Common Xpress Port Logic (CXPL) and Transmit Application-Dependent Module (XADM).

48.3.3.1 Transmit Overview

Generally, all types of transmit TLPs (Posted, Non-Posted, and Completion) generated by the application travel through the core in the following flow:

1. The application presents a transaction transmission request with header information and payload (if applicable) on one of the transmit client interfaces (for example, XALI0).
2. The XADM forms the transaction into a TLP and checks the TLP against the current Flow Control credit availability. If the TLP passes the Flow Control checks and wins the arbitration with TLPs from the other the client interfaces, then the TLP goes to the CXPL.
3. The XTLH module inserts an ECRC (if applicable) and snoops/stores the necessary TLP information for Completion lookup (for Non-Posted requests only).
4. The XDLH inserts the Sequence Number and LCRC into the TLP and the retry buffer stores the TLP.
5. The XMLH inserts start and end delimiters and performs data scrambling.
6. The XMLH presents the packet to the PHY through the PIPE interface.
7. The PHY receives the packet, performs 8b10b encoding, and serialization, then sends the packet for transmission on the Link

The core does not check for TLP errors; instead it sends the TLP as presented on the XALI interface.

The native PCIe core does not check that the TLP payload size is less than the 'Maximum Payload Size' limit. However, the AXI bridge module does guarantee that this limit is not exceeded.

The native PCIe core does not check that the TLP payload size is less than CX_MAX_MTU limit. Exceeding this limit will overflow the retry buffer, resulting in data corruption. However, the AXI/AHB bridge module does guarantee that this limit is not exceeded.

48.3.3.2 Transmit TLP Arbitration

The transmit arbitration mechanisms supported by the core are as follows:

- Client-based round robin arbitration
- Strict priority client-based arbitration
- VC-based priority arbitration

To configure the transmit arbitration algorithm, use the 'Transmit Arbitration Method' configuration parameter (`CX_XADM_ARB_MODE).

Regardless of the transmit arbitration method selected, Messages (both internally-generated and Messages requested through the VMI) always have the highest priority, followed by internally-generated Completions. The priority order for all transmitted TLPs is:

1. Internally generated Messages
2. Internally-generated Completions
3. Transmit TLPs from Client0, Client1, and Client2 according to the selected arbitration method

48.3.3.2.1 Client-Based Arbitration

When you configure the core to use client-based arbitration (`CX_XADM_ARB_MODE = 1), the XADM uses round-robin arbitration between the two transmit client interfaces.

48.3.3.3 Transmit Retry

There is a Retry Buffer (RB) in the core that stores a copy of each transmitted TLP until an Ack is received. The RB consists of two buffers: retry buffer and start-of-TLP (SOT) buffer.

NOTE

The Retry Buffer does not function as a transmit queue. The core transmits TLPs immediately after they pass arbitration. The copy in the Retry Buffer is only sent in the event that the TLP must be re- transmitted.

The retry buffer is implemented with a single port RAM. The depth of the retry buffer is selected during hardware configuration either by enabling automatic buffer sizing or by setting the depth explicitly. The retry buffer width is set automatically (data bus width plus extra control bits).

The selected retry buffer size determines the size of the SOT buffer. The SOT buffer stores the starting address of each unacknowledged TLP stored in the retry buffer. The SOT buffer is implemented with a single port RAM and is indexed by the Sequence Number of the TLP whose starting address is being stored or retrieved.

The minimum depth of the SOT buffer is also a user configuration option. The selected size must allow the retry buffer to store the maximum number of shortest TLPs (3 DWORDs).

When a Nak is received or the replay timer times out, a replay is initiated. A replay is terminated by two conditions:

- When the replay of all TLPs in the retry buffer is finished, or
- An Ack DLLP is received that acknowledges all TLPs in the retry buffer

The replay timer tracks the TLP replay time. It stays at 0 when every TLP has received an Ack and starts to count when a TLP is transmitted and the LTSSM is not in the training state. The replay timer is reset to 0 when an Ack or Nak is received that acknowledges a TLP that is in the retry buffer.

48.3.3.4 Transmit DLLP Priorities

The order of priority to transmit pending DLLPs is:

1. High-priority DLLPs
2. TLPs
3. Low-priority DLLPs

48.3.4 Receive TLP Processing

The information found here describes the flow of receive TLPs through the core.

48.3.4.1 Receive Overview

It may helpful to first review the following sections:Common Xpress Port Logic (CXPL) and Receive Application-Dependent Module (RADM).

Generally, received transactions travel through the core in the following flow:

1. The PHY receives a stream of bits and aligns/forms them into 10-bit symbols (Gen1/2)
2. The PHY decodes the 10b stream into an 8b stream (Gen1/2)
3. The PHY crosses the clock domain from RX to TX and presents the stream to the PIPE.
4. The RMLH descrambles and deskews the incoming data, checks for receiver (Gen1/2) then extracts packets.
5. The RDLH strips off the LCRC and Sequence Number.
6. The RTLH strips off the ECRC (if applicable), checks for a malformed TLP, and forms a transaction across the RTLI interface to the RADM.

7. The RADM filters the transaction based on the transaction type (Posted, Non-Posted, or Completion) and the rules described in Receive Filtering.
8. Filtered transactions are sent to RADM queues.
9. Transactions residing in the RADM queues are presented to the application or locally handled by the LBC module, depending upon the filter result

48.3.4.2 Receive Filtering

The core contains a filter module that is responsible for the tasks listed here.

- Determine the status of a received TLP using filtering rules.
- Determine the destination interfaces of a received TLP based on the status from applying the filter rules.
- Signal the application for the status of the received TLP by driving signals such as DLLP abort, TLP abort and ECRC error.

The core filters and routes received TLPs according to a set of rules determined by the TLP type based on the *PCI Express Base 3.0 Specification* and user-configurable filtering options. The filtering rules for a received TLP are affected by I/O signals (run-time options), and register values (run-time options).

The application can mask some of the filtering and error handling rules by setting the corresponding bits in Symbol Timer Register and Filter Mask Register 1 and Filter Mask Register 2.

There are three types of the filtering rules in the core:

- 3.4.2.1: rules that are applicable for all TLP received
- 3.4.2.2: rules that are dependent on the type of the TLP based on PCIe specification
- 3.4.2.3: rules that are not from the PCIe specification but requested by specific applications.

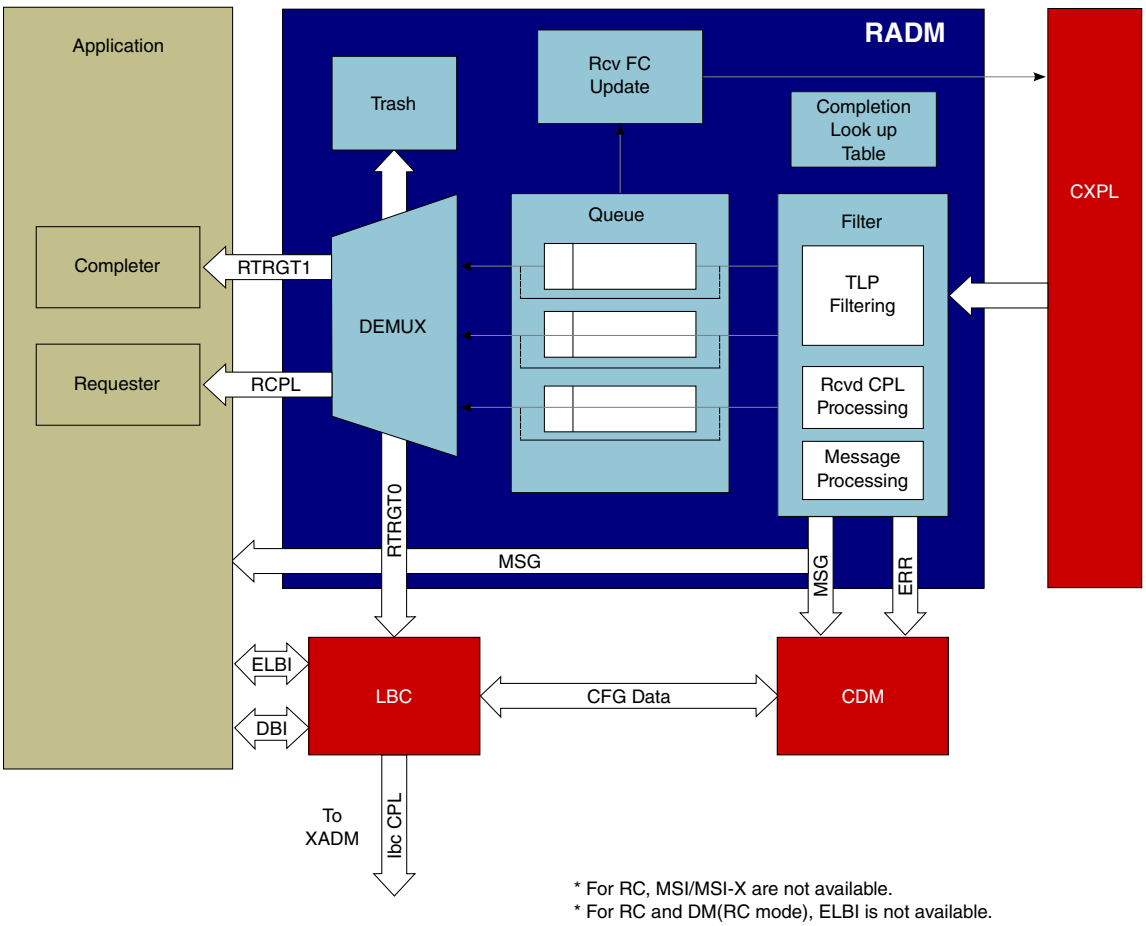

Figure 48-11. RADM Block Diagram

48.3.4.2.1 Filtering Rules Applicable for all TLPs Received

The general rules listed here apply to all incoming TLPs.

- The core discards all incoming TLPs that have an invalid Type field. This TLP is treated as a 'TLP ABORT'.
- By default, a request TLP with the poison bit set (EP=1) is considered an Unsupported Request (UR) and discarded, as the poison rule mask bit (CX_FLT_MASK_UR_POIS) is not set in the Symbol Timer Register and Filter Mask Register 1. You can control the end result of a poisoned TLP by setting this mask bit, and having the poisoned TLP sent to your application.
- A locally terminated TLP with ECRC error detected is discarded in store-and-forward mode and an ECRC error reported only when the filter mask CX_FLT_MASK_ECRC_DISCARD bit is not set. For more information see ECRC Handling.
- Filter rules have no effect on received TLPs when 'DLLP ABORT' signal is asserted.

- If a completion of a non-posted request is not received within a completion timeout period, this request will be treated as a completion timeout, and a non-advisory error will be reported.
- For messages to be accepted and decoded, the incoming Message must be one of the valid Message types with the correct payload length based on *PCIe 3.0 Specification*. Valid Messages will be decoded and passed onto the SII interface as necessary.

See Error Handling for more details.

The filtering rules for an incoming Request TLP are affected by the configuration parameters (compile-time options), I/O signals (run-time options), and register values (run-time options).

NOTE

In many cases, the standard filtering rules may be 'masked' or ignored by setting the corresponding bit in the Symbol Timer Register and Filter Mask Register 1 and Filter Mask Register 2, which take their default values from the DEFAULT_FILTER_MASK_1 and DEFAULT_FILTER_MASK_2 configuration parameters.

48.3.4.2.2 Filtering Rules Based on TLP Type Defined in PCIe Specification

PCIe TLPs are categorized as Requests and Completions. The table found here describes the filtering rules for Request and Completion TLPs and the results of the core's filter.

If a received TLP passes all of the filter rules for Request and Completion TLPs, then it is considered to have no errors, and the TLP will be routed to the destination that is configured. Details on routing are provided in Receive Routing.

Notation of filter results:

1. UR = Unsupported Request

   CA = Completer Abort

   CRS = Configuration Request Retry Status

   SU = Successful

   UC = Unexpected Completion

   MLF = Malformed

   '-' = Filtering rule does not apply to TLP type

   MA = Master Abort

TA = Target Abort

48.3.4.2.2.1 EP MODE FILTERING RULES

Table 48-3. Result of Filtering Rules Applied to Request TLPs and Completion (CPL) TLPs: EP Mode

Filtering Rule	TLP Type					
	MRd IORd	MWr IOWr	CFG	MSG	CPL with UR/CA/CRS status	CPL with SU status
PowerState is not in D0.	UR	UR	SU	SU	UC	UC
Address is not within any configured Memory BAR or IO BAR if it is an IO request.	UR	UR	-	-	-	-
TLP header poison bit is set and the filter mask CX_FLT_MASK_UR_POIS bit is not set.	UR	UR	UR	UR	SU	SU
Address within a BAR that is configured to RTRGT0 and TLP DW length > 1.	CA	CA	-	-	-	-
MRd with lock and filter mask CX_FLT_MASK_LOCKED_RD_AS_UR bit is not set.	UR	-	-	-	-	-
The function number of a completer ID within a CFG request does not match an implemented function within the receiver device and the filter mask CX_FLT_MASK_UR_FUNC_MISMATCH bit is not set.	-	-	UR	-	-	-
Configuration type1 TLP request and the filter mask CX_FLT_MASK_CFG_TYPE1_REQ_AS_UR is not set.	-	-	UR	-	-	-
Application requests the core filter to return CRS by asserting signal app_req_retry_en.	-	-	CRS	-	-	-
Not Valid Message for EP device	-	-	-	UR/MLF	-	-
Illegal payload length of a message.	-	-	-	UR	-	-
Vendor MSG Type0 with filter mask CX_FLT_MASK_VENMSG0_DROP bit not set.	-	-	-	UR	-	-
Vendor MSG Type1 with r[2:0] to 3'b010 and {Bus#, Dev#, Func#} mis-match.	-	-	-	UR	-	-
TLP with ECRC error detected	CA	CA	CA	-	-	-
Requester ID mis-match	-	-	-	-	MA/TA	MLF
Requester TAG mis-match	-	-	-	-	MA/TA	MLF
TAG error (non-pad zero for reserved TAG bits	-	-	-	-	MA/TA	MLF
Byte Count Mismatch (PCIe Gen2)	-	-	-	-	MA/TA	UC/MLF

Table 48-4. Result of Filtering Rules Applied to Request TLPs and Completion (CPL) TLPs: EP Mode

Filtering Rule	TLP Type					
	MRd IORd	MWr IOWr	CFG	MSG	CPL with UR/CA/CRS status	CPL with SU status
Completion received with status of UR.	-	-	-	-	MA	-
Completion received with status of CA.	-	-	-	-	TA	-
Completion received with status of CRS	-	-	-	-	CRS	-
Completion received with CRS status and Completion is not a pending configuration request	-	-	-	-	MLF	-

A complete list of the filtering checks can be referenced at Symbol Timer Register and Filter Mask Register 1 (PCIE_PL_STRFM1) and Filter Mask Register 2 (PCIE_PL_STRFM2).

48.3.4.2.2.2 RC MODE FILTERING RULES

Table 48-5. Result of Filtering Rules Applied to Request TLPs and Completion (CPL) TLPs: RC Mode

Filtering Rule	TLP Type							
	MRd	MWr	CFG[1]	IO	MSG	CPL with UR/CA status	CPL with CRS status	CPL with SU status
Address does not satisfy any of the following conditions: 1. Within any configured Memory BAR. 2. Outside of the memory range AND prefetchable memory range as determined by the corresponding Base and Limit fields in the Type-1 header. 3. The filter mask CX_FLT_MASK_UR_OUTSIDE_BAR bit is set, which treats out-of-bar TLPs as Supported Requests and indicates a special application requirement	UR	UR	-	-	-	-	-	-
Native Core (no AHB/AXI bridge): FLT_Q_ADDR_WIDTH < 64, and any upper address bit (above bit position FLT_Q_ADDR_WIDTH-1) is set to '1'	UR	UR	-	UR	-	-	-	-
With AHB/AXI bridge: MASTER_BUS_ADDR_WIDTH = 32, FLT_Q_ADDR_WIDTH > 32,	UR	UR	-	UR	-	-	-	-

Table continues on the next page...

Table 48-5. Result of Filtering Rules Applied to Request TLPs and Completion (CPL) TLPs: RC Mode (continued)

and any upper address bit (above bit position MASTER_BUS_ADDR_WIDTH-1) is set to '1'								
TLP header poison bit is set and the filter mask CX_FLT_MASK_UR_POIS bit is not set.	UR	UR	UR	UR	UR	-	-	-
MRdLk request received and filter mask CX_FLT_MASK_LOCKED_RD_AS_UR bit is set, which indicates that customer prefer to filter out the MRdLk.	UR	-	-	-	-	-	-	-
CFG Request received and the filter mask CX_FLT_MASK_RC_CFG_DISCARD is not set	-	-	UR	-	-	-	-	-
IO Request received and the filter mask CX_FLT_MASK_RC_IO_DISCARD is not set	-	-	-	UR	-	-	-	-

Table 48-6. Result of Filtering Rules Applied to Request TLPs and Completion (CPL) TLPs: RC Mode

Filtering Rule	TLP Type							
	MRd	MWr	CFG[1]	IO	MSG	CPL with UR/CA status	CPL with CRS status	CPL with SU status
Vendor MSG Type0 with filter mask CX_FLT_MASK_VENMSG0_DROP bit not set.	-	-	-	-	UR	-	-	-
Not Valid Message for RC device	-	-	-	-	UR/MLF	-	-	-
TLP with ECRC error detected	CA	CA	CA	CA	-	-	-	-
Requester ID mis-match	-	-	-	-	-	MA/TA	-	MLF
Requester TAG mis-match	-	-	-	-	-	MA/TA	-	MLF
TAG error (non-pad zero for reserved TAG bits	-	-	-	-	-	MA/TA	-	MLF
Byte Count Mismatch	-	-	-	-	-	MA/TA	-	MLF
Completion received with status of UR.	-	-	-	-	-	MA	-	-
Completion received with status of CA.	-	-	-	-	-	TA	-	-
Completion received with CRS status and Completion is not a pending configuration request.	-	-	-	-	-	-	MLF	-

1. DM (in RC mode) should not expect to receive a CFG or IO request.

48.3.4.2.3 Filtering Rules Not Defined in PCIe Specification

There are additional filtering rules that are designed to provide enhanced filter support for certain applications.

- Core to handle the received posted or non-posted requests with zero byte length. When a zero-byte request TLP is received, also called "flush" command, the core can drop[1] the zero- byte request. This is designed to support some applications that can not handle a zero-byte request. Applications can dynamically program a bit in the filter mask CX_FLT_MASK_HANDLE_FLUSH bit to turn on/off this rule. If the core is programmed to handle the flush, it will be the completer's task to return completion status.
- Core to detect oversize read request and return UR for the read request.Some applications may have a buffer limit and are not able to handle lengthy read requests. The core over-size read request detection rule can be turned on when an application can identify a maximum read request size that it can tolerate.

48.3.4.3 Receive Routing

48.3.4.3.1 EP Mode

The possible destinations of a posted or non-posted Request TLP are RTRGT1 interface, RTRGT0 interface and Core Discard (dropped[1] or terminated). By default:

- CFG requests are routed to RTRGT0 and then to CDM via LBC.
- BAR-matched MEM/IO requests are routed to RTRGT1.
- MSG requests are decoded internally, signalled on the SII interface and then terminated.

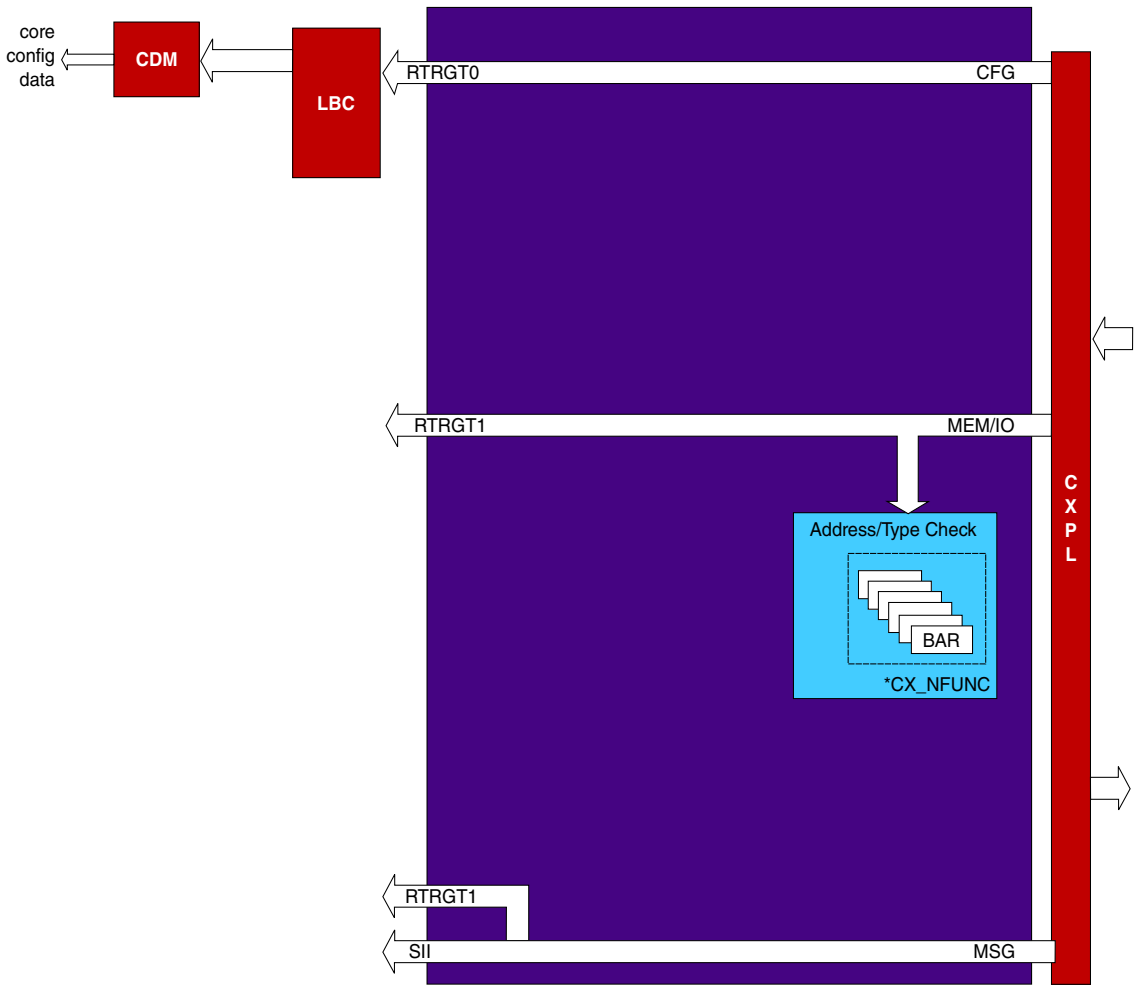

Figure 48-12. Default Request TLP Routing (assuming no TLPs with CA/CRS/UR completion status)

The possible destinations of a Completion TLP are RCPL interface, RBYP interface, RTRGT1 interface, and Core Discard.

In general, a TLP type that is configured as bypass will be sent to either the RBYP interface, or RCPL interface if it is a completion. A TLP type that is configured as a cut-through or store-forward will be sent to RTRGT1 interface.

Because the core supports three types of queue architecture (single queue, multiple queue, segmented buffer queue architecture) and three buffer modes (bypass, cut-through, store-forward mode), a configuration of the core receive queue structure will affect the destination of a received TLP.

NOTE

By default, all Configuration Requests that pass filtering go to RTRGT0 for configuration register access. However, the application can configure the core to direct certain

configuration TLPs to the RTRGT1 interface - see PCIe Wire Access (EP mode) for more details. The application is responsible for generating Completions for Configuration Requests that are routed to RTRGT1.

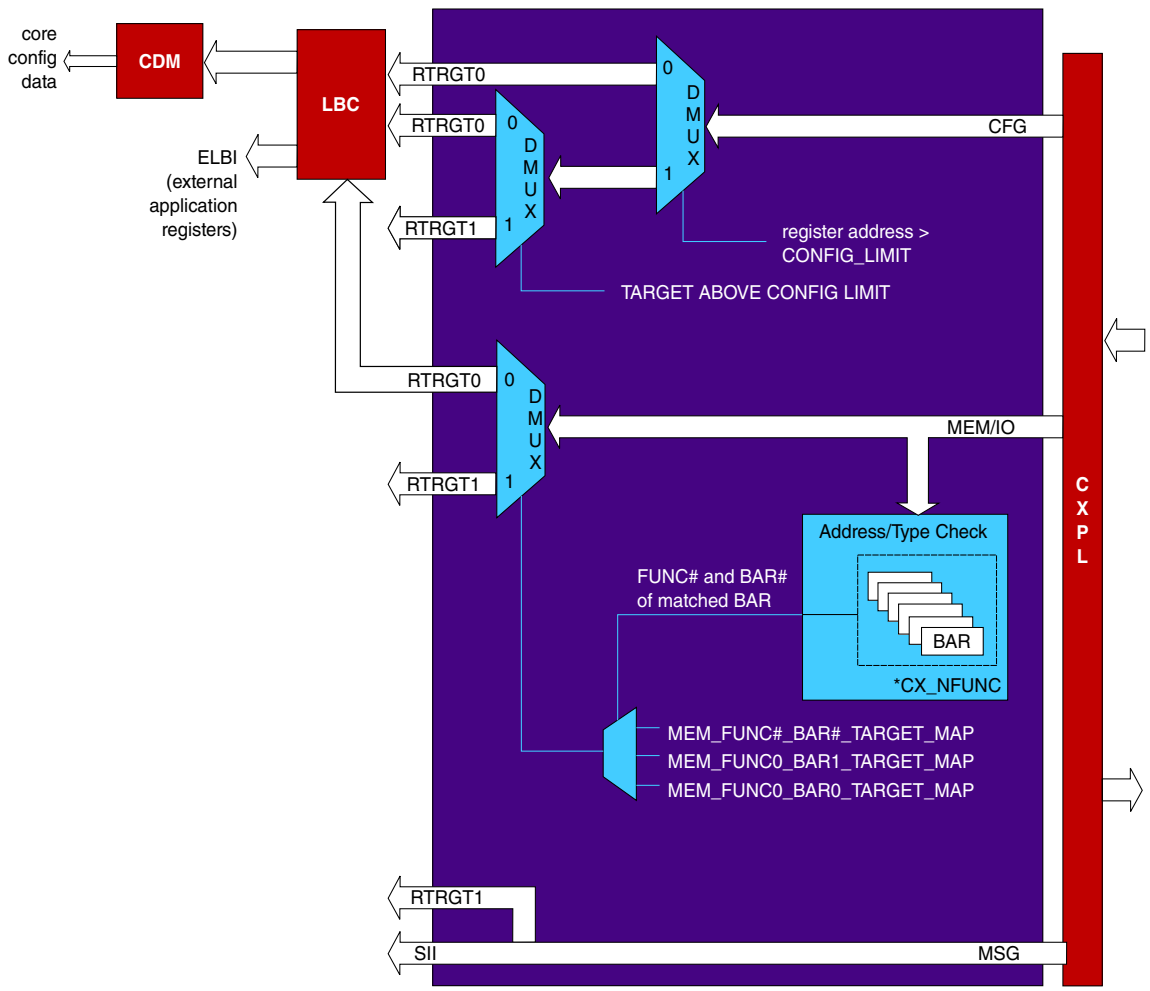

Figure 48-13. Configurable Request TLP Routing (assuming SC completion status).

48.3.4.3.2 RC mode

The possible destinations of a posted or non-posted Request TLP are RTRGT1 interface and Core Discard (dropped1 or terminated). By default:

- MEM requests outside of the memory range AND prefetchable memory range as determined by the corresponding Base and Limit fields in the Type-1 header, are routed to RTRGT1.
- MSG requests are decoded internally, signalled on the SII interface and then terminated.

- An RC does not expect to receive CFG or IO requests.
- BARs should be disabled and not used.

The possible destinations of a Completion TLP are RCPL interface, RBYP interface, RTRGT1 interface, and Core Discard.

In general, a TLP type that is configured as bypass will be sent to the RBYP interface. A TLP type that is configured as a cut-through or store-forward will be sent to RTRGT1 interface. Because the core supports three types of queue architecture (single queue, multiple queue, segmented buffer queue architecture) and three buffer modes (bypass, cut-through, store-forward mode), a configuration of the core receive queue structure will affect the destination of a received TLP.

48.3.4.3.3 ECRC Handling

The setting of the CX_FLT_MASK_ECRC_DISCARD bit (default value is 0) in the Symbol Timer Register and Filter Mask Register 1 can be used to prevent an ECRC contributing to a CA status and thereby preventing all associated downstream effects such as error handling.

By default, all incoming IO or MEM requests with UR/CA/CRS status will be dropped1/ terminated and an Advisory Non-Fatal Error is signalled. For Non Posted (NP) requests, a CPL with CA is generated. See Advisory Non-Fatal Error Messages.

If you set the DEFAULT_TARGET parameter to 'Forward' (default is 'Drop'), then all incoming IO or MEM requests with UR/CA/CRS status will not be dropped but will be forwarded to the application. Setting CX_MASK_UR_CA_4_TRGT1 (default is 0) at the same time, will suppress error reporting for TLPs (with UR/CA status) that are being routed to the application on AXI Bridge master.

A completion TLP with ECRC errors is only dropped by the RADM in the native core when CPL queue mode is store-forward and queue architecture is single or multiple queue. See Completion TLP Routing Rules for more details.

48.3.4.3.4 Request TLP Routing Rules

The next table shows the applicability of routing rules for Request TLPs, and indicates whether the destination is as stated by the rule when the conditions of the rule are met.

By default all error-free MSG requests are decoded internally, signalled on the SII interface and then terminated. To have the decoded message *also* sent to the application/ AMBA interface then see Routing of Received Messages to SII and optionally to

Application. When a MSG request is filtered with UR/CA/CRS status, the TLP is always terminated. Only MSG requests filtered with SC status, can potentially be forwarded to the application.

For a full analysis of what error conditions contribute towards an UR or CA status, see Receive Filtering. For example, an ECRC error contributes towards a CA status whereas an UR status can be generated by detecting the EP bit set in the TLP header or having an IO/MEM request not match against any of the BARs.

In many cases, the standard routing rules may be 'masked' or ignored by setting the corresponding bit in the Symbol Timer Register and Filter Mask Register 1 and îFilter Mask Register 2. For example, see Message Reception.

NOTE

RTRGT1 is the application interface and it is connected to the AXI bridge master interface.

Notation of routing results:

Yes = destination is as specified in rule when conditions of rule are met

no = destination is not as specified in rule even when conditions of rule are met

- = routing rule has no affect because it does not apply to TLP type

Table 48-7. Routing Rules for Request TLPs (EP Mode)

Routing Rule	MRd	MWr	CFG	IO	Vendor MSG Type0	Vendor MSG Type1	Other MSG
When a request is filtered with SU status, and is in BAR range, MEM_FUNC#_BAR#_TARGET_MAP parameter determines the destination.	Yes	Yes	no	Yes	-	-	-
When a request is filtered with UR/CA/CRS status, and the DEFAULT_TARGET parameter is 0, the TLP is dropped. For NP requests, a CPL is also generated.	Yes	Yes	Yes	Yes	Yes	Yes	Yes
When a request is filtered with UR/CA/CRS status, and the DEFAULT_TARGET parameter is 1, the TLP is dropped.	no	no	no	no	Yes	Yes	Yes
When a request is filtered with UR/CA/CRS status, and the DEFAULT_TARGET parameter is 1, the destination is RTRGT1 interface.	Yes	Yes	Yes	Yes	no	no	no
When a CFG request is filtered with SU status and the CFG register address is > CONFIG_LIMIT, TARGET_ABOVE_CONFIG determines the destination.	-	-	Yes	-	-	-	-

Table continues on the next page...

Table 48-7. Routing Rules for Request TLPs (EP Mode) (continued)

When a CFG request is filtered with SU status and the CFG register address is < CONFIG_LIMIT, RTRGT0 interface is the destination.	-	-	Yes	-	-	-	--
The TLP is dropped, when the filter mask CX_FLT_MASK_MSG_DROP bit is not set and the non-Vendor MSG is filtered with SU status.	-	-	-	-	no	no	Yes
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG0_DROP bit is 0 and the VEN0 MSG is filtered with SC status.	-	-	-	-	Yes	no	no
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG1_DROP bit is 0 and the VEN1 MSG is filtered with SC status. RTRGT1 interface is the destination when none of the previous rules are satisfied and the MSG is filtered with SU status.	- -	- -	- -	- -	no Yes	Yes Yes	no Yes

Table 48-8. Routing Rules for Request TLPs (RC mode)

Routing Rule	MRd	MWr	[1]CFG	[1]IO	Vendor MSG Type0	Vendor MSG Type1	Other MSG
When a request is filtered with SU status, and is not in BAR range, RTRGT1 is the destination.	Yes	Yes	no	Yes	-	-	-
[2]When a request is filtered with SU status, and is in BAR range, MEM_FUNC#_BAR#_TARGET_MAP parameter determines the destination.	Yes	Yes	no	no	-	-	-
When a request is filtered with UR/CA status, the TLP is dropped. For NP requests, a CPL is also generated.	Yes	Yes	Yes	Yes	Yes	Yes	Yes
The TLP is dropped, when the filter mask CX_FLT_MASK_MSG_DROP bit is 0 and the non-Vendor MSG is filtered with SU status.	-	-	-	-	no	no	Yes
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG0_DROP bit is 0 and the VEN0 MSG is filtered with SU status.	-	-	-	-	Yes	no	no
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG1_DROP bit is 0 and the VEN1 MSG is filtered with SU status. RTRGT1 interface is the destination when none of the previous rules are satisfied and the MSG is filtered with SU status.	- -	- -	- -	- -	no Yes	Yes Yes	no Yes

1. DM (in RC mode) should not expect to receive a CFG or IO request.

2. BARs are not normally used in RC application.

48.3.4.3.5 Completion TLP Routing Rules

The table found here shows the applicability of routing rules for Completion TLPs, and indicates whether the destination is as stated by the rule when the conditions of the rule are met.

In summary, under error conditions, CPLs are never dropped but always forwarded to the application except when:

1. 'suggested' completion or error status is any of the following:
   - UC
   - 'DLLP abort'
   - 'ECRC error'

   and

2. queue mode is store-forward and
3. queue architecture is single or multiple queue.

Table 48-9. Routing Rules for Completion TLPs.

Routing Rule	Filter Status of the Completion (CPL)	
	SC / UR / CA / CRS	UC / 'DLLP abort' / 'ECRC error'
Core Drop is the destination when queue mode is store-forward and queue architecture is single queue or multiple queue	no	yes
RCPL interface is the destination when queue mode is <any> and queue architecture is single queue or multiple queue	yes	yes
RBYP interface is the destination when queue mode is by-pass and queue architecture is segment buffer queue.	yes	no
RTRGT1 interface is the destination when queue mode is cut-through and queue architecture is segment buffer queue.	yes	no
RTRGT1 interface is the destination when queue mode is store-forward and queue architecture is segment buffer queue.	yes	no
Core Drop is the destination when queue mode is <any> and queue architecture is segment buffer queue.	no	yes

48.3.4.4 Receive Queuing

The core support three configurable queue architectures per VC: single queue, multiple queue, and segmented queue.

Each queue architecture supports three buffering modes: bypass mode, cut-through mode, and store-and-forward mode. The buffering mode is selectable for each TLP type: posted, non-posted and completion. The configurability is dependent on the queuing architecture.

The single queue architecture has one header buffer and one data buffer; and the header and data buffers are used as a single FIFO for buffering all posted, non-posted and completion TLP.

The multiple queue architecture has a single header and data buffer per posted, non-posted and completion TLP type.

The segmented queue architecture has one header buffer and one data buffer, but these two buffers are segmented by posted, non-posted and completion TLP type (versus single queue architecture).

For all queuing modes, RAM modules are either instantiated inside the top-level module of the core or connected externally, which is configurable.

48.3.4.4.1 Queuing Architecture

The queue architecture is specified by the user using the CX_RADMQ_MODE configuration parameter..

48.3.4.4.1.1 SEGMENTED-BUFFER RECEIVE QUEUE CONFIGURATION (CX_RADMQ_MODE=2)

The segmented-buffer queue architecture is designed for applications that want to enforce an ordering rule other than FIFO. This is the only queue architecture that can strictly adhere to the ordering rules of the *PCI Express Specification*. This queue architecture is relatively large in area. The segmented-buffer configuration uses a single memory module pair (header and data) for all TLP types and all VCs.

In the segmented-buffer configuration:

- The memory width is set automatically.
- The memory is divided into segments for Posted, Non-Posted, and Completion queues for each VC. The depth of each segment is set during hardware configuration,
- The operating mode is selected (bypass, cut-through, or store-and-forward) independently for each TLP type of each VC during hardware configuration. The operating mode (per TLP type and VC) can be controlled dynamically by writing to the Port Logic registers. If a TLP type is configured to be cut-through or store-and-forward, then it will be routed to the RTGT interfaces. If a TLP type is configured to be bypassed, then it will be routed to the radm_bypass interface. Once a Posted Request is configured in bypass mode, the application should not expect to send a Posted-write to the ELBI interface.

- The number of advertised credits is selected independently for each TLP type and each VC during hardware configuration. The number can be selected dynamically by writing to the Port Logic registers.
- The receive queue priority for VCs can be set to either strict priority (higher-numbered VCs have higher priority) or round robin during hardware configuration; and the priority at runtime can be set by writing to the Port Logic registers.
- The ordering rules for TLP types can be set during hardware configuration and at runtime by writing to the Port Logic registers. The choices are either strict priority (Posted first, Completion second, Non-Posted third) or priority determined according to ordering rules set forth in the PCI Express 3.0 Specification.

48.3.4.4.2 Queue Modes

The queue mode for each P/NP/CPL queue is specified using the RADM_P_QMODE_VC0 , RADM_NP_QMODE_VC0 and RADM_CPL_QMODE_VC0 configuration parameters.

It is possible to change the Queue Mode (during device setup by software) by writing to the appropriate queue control register.

BYPASS MODE (RADM_P/NP/CPL_QMODE_VC0=4)

Queues in bypass mode are completely bypassed.

In the case of aborted TLPs, the core asserts either radm_trgt1/cpl/bypass_dllp_abort or radm_trgt1/cpl/bypass_tlp_abort to the application. The application is responsible for rolling back any actions that were performed on behalf of the aborted TLP.

CUT-THROUGH MODE (RADM_P/NP/CPL_QMODE_VC0=2)

In cut-through mode, the queue presents data to the application as soon as the first data for a packet is placed into the queue.

In the case of aborted TLPs, the application is responsible for rolling back any actions that were performed on behalf of the aborted TLP. The radm_trgt1/cpl/bypass_dllp_abort and radm_trgt1/cpl/bypass_tlp_abort signals are presented to the application at the same time as the eot signal.

STORE-AND-FORWARD MODE (RADM_P/NP/CPL_QMODE_VC0=1)

In store-and-forward mode, only valid TLPs are forwarded to the application logic. Therefore, no rollback functionality is required by the application. All TLPs with radm_trgt1/cpl/bypass_dllp_abort or radm_trgt1/cpl/bypass_tlp_abort asserted will be dropped[1] by the receive queues of the core.

Flow Control credits are returned by the queue as packets are read out (even when the TLP was aborted and not presented to the application).

NOTE

Error handling by the application is dependent on the choice of queue mode. See Dependency upon Queue Architecture and Mode.

48.3.4.4.3 Order Enforcement

The ordering of TLPs within the same VC depends on the queuing architecture as follows:

- In the segmented-buffer configuration, either PCIe ordering rules or strict priority ordering are provided.
- In segmented buffer mode, you may select either strict VC priority (same as for single- and multi- buffer) or round robin.

For more information of packet ordering in relation to buffering/queue mode and architecture see:

- App Note: Order Enforcement Using the PCIe Core
- Inbound Order Enforcement for AXI Bridge

48.3.4.4.4 Queue to Port Mapping

Tables found here indicate which interfaces (ports) are used to deliver requests and completions depending on the queue architecture and buffer mode selected.

For Posted (P) and Non Posted (NP) TLP's, the destination (RTRGT1/RTRGT0) depends on the BAR setup, and if the TLP is of CFG type or not.

See Receive Routing for more details on routing for TLP's under error conditions.

QUEUE TO PORT MAPPING WHEN AHB/AXI BRIDGE PRESENT

RTRGT1 is connected to the AXI/AHB Bridge master interface (request) channel. RCPL and RBYP are connected to the AXI/AHB Bridge slave interface (response) channel. See Receive Routing for more details on routing for TLP's under error conditions.

Table 48-10. Segmented Queue Architecture (CX_RADMQ_MODE == 2) Queue to Port Mapping

Queue Mode	Posted	Non Posted	CPL

Table continues on the next page...

Table 48-10. Segmented Queue Architecture (CX_RADMQ_MODE == 2) Queue to Port Mapping (continued)

(RADM_P/NP/CPL_QMODE_VC0)	TLP Queue	TLP Queue	Queue
Store and Forward (1)	RTRGT1 / RTRGT0	RTRGT1 / RTRGT0	[1]RTRGT1
Cut Through (2)	n/a	n/a	n/a
Bypass (4)	n/a	n/a	RBYP

1. Use this feature if you want to maintain PCI Express ordering rules within the AHB/AXI Bridge module after packets have left the RADM receive queues in the native PCIe core. For more information see Ordering Enforcement Hardware Lock Feature.

48.3.5 Error Handling

An overview and additional information regarding error handling can be found here.

48.3.5.1 Error Handling Overview

Errors are classified into two levels:

- Correctable Error (CORR). This means that the PCIe core has a way of automatically handling the error. There is no loss of information. For example, Link CRC (LCRC) that is fixed by replaying the DLL.
- Uncorrectable Error (UNCORR). The PCIe core can not fix these and they are classified as:
- Fatal Error (FATAL). The link is not functioning correctly and may require a link reset.
- Non-Fatal Error (NONFATAL). The problem is not related to link operation.

The core implements the types of error handling found here.

- PCIe Baseline Capability. These reporting capabilities are a minimum set, and are required of all PCI Express devices. Error notification takes two forms:
- Messages sent to Root Complex (RC).
- Completion Status errors.

This also covers mapping of PCIe errors to legacy PCI generic error handling such as PERR# and SERR#. Many of the PCIe errors are mapped into the Status register in the PCI Compatible Configuration Space Header.

- PCIe Advanced Error Reporting (AER) Capability. Allows more sophisticated error reporting, control, masking and logging using the PCIe extended AER capability register structure.

The PCIe core supports Advisory reporting for both the Baseline and AER capabilities, which is the configurable with-holding of reporting for Non-Fatal errors (NONFATAL).

For an RC port, the reporting of most errors is internal to the root port. No external error notifications are generated. One exception to this (for example) is Unsupported Request (UR) completion status.

48.3.5.2 PCIe Baseline Capability

Reporting of errors is achieved by sending a notification to the RC (a CPL with UR/CA/CRS status for Non Posted requests, and optionally an error Msg).

The decision to send an error MSG is controlled by a complex set of associated control and status bits. The status is also logged in the Device Status Register for the following errors: Unsupported Request (UR), FATAL, NONFATAL and CORR.

MESSAGES SENT TO ROOT COMPLEX (RC).

Messages sent to the RC are of the ERR_CORR, ERR_NONFATAL, and ERR_FATAL types.

COMPLETION STATUS ERRORS.

Completion Status errors for Non Posted requests may be any of the following:

- Unsupported Request (UR)
- Configuration Request Retry Status (CRS)
- Completer Abort (CA)

REPORTING THROUGH THE DEVICE STATUS REGISTER

The PCI Express Capability Register Structure provides the following support for Baseline Error Reporting.

- Enable/disable error reporting (Device Control Register).
- Provide error status (Device Status Register) for:
- UR
- Correctable Error (CORR).
- Fatal Error (FATAL).
- Non-Fatal Error (NONFATAL).
- A method for software to force Link Retraining (Device Control Register).

48.3.5.3 Advanced Error Reporting (AER)

The decision to send an error MSG is controlled by a complex set of associated control and status bits. For more details, see the flow diagram in Error Detection. AER allows more sophisticated error reporting, control, masking and logging using the optional extended AER capability register structure. By default, AER is enabled (AER_ENABLE parameter), and may not be disabled unless you disable ECRC support in the core (CX_ECRC_ENABLE parameter).

AER REGISTERS

The AER registers are described in the Advanced Error Reporting Capability Registers section described in . All possible errors are enabled, masked and assigned a severity.

There are two sets of registers:

- Error Enable Register
- Error Severity Register
- Error Mask Register.

The Correctable set of registers handles (for example) errors arising from bad DLLPs or TLPs.

The Uncorrectable set of registers handles (for example) errors arising from UR, ECRC, Malformed TLPs, Buffer Overflow, UC, CA, Completion Timeout and Poisoned TLP.

SEVERITY PROGRAMMING

The Uncorrectable Error Severity register allows each uncorrectable error to be programmed to Fatal or Non-Fatal. The transmission of these error Messages by class (correctable, non-fatal, fatal) is enabled using the Reporting Enable fields of the Device Control register or the SERR# Enable bit in the PCI Command register.

The Uncorrectable Error Mask register and Correctable Error Mask register allows each error condition to be masked independently. If Messages for a particular class of error are not enabled by the combined settings in the Device Control register and the PCI Command register, then no Messages of that class will be sent regardless of the values for the corresponding mask register. If an individual error is masked when it is detected, its error status bit is still affected, but no error reporting Message is sent to the Root Complex, and the Header Log and First Error Pointer registers are unmodified.

48.3.5.3.1 Advisory Non-Fatal Error Messages

The PCIe core supports Advisory reporting which is the configurable with-holding of reporting for Non- Fatal errors.

- With Baseline Error Reporting, the core produces no error message.
- With AER, the core can instead, signal a non-fatal error with ERR_COR, which serves as an advisory notification to software.

It will always signal a fatal error with ERR_FATAL

UR/CA ADVISORY

The PCIe core generally sends a CPL with UR/CA status to signal a uncorrectable error for a Non-Posted Request. If the severity of the UR/CA error is non-fatal, the PCIe core will handle this case as an Advisory Non-Fatal Error.

By default, the PCIe core will signal the non-fatal error (if enabled) by sending an ERR_COR Message.

If AER is disabled (AER_ENABLE=0), the PCIe core sends no error Message for this case. Even though there was an uncorrectable error for this specific transaction, the PCIe core will handle this case as an Advisory Non-Fatal Error, since the Requester upon receiving the Completion with UR/CA Status is responsible for reporting the error (if necessary) using a Requester-specific mechanism.

UC ADVISORY

When the PCIe core receives an UC and the severity of the UC error is non-fatal, the PCIe core will handle this case as an Advisory Non-Fatal Error. By default, the PCIe core will signal the error (if enabled) by sending an ERR_COR Message.

If AER is disabled (AER_ENABLE=0), the PCIe core sends no error Message for this case.

48.3.5.4 Error Source Classification

The table found here indicates how some of the more common low level errors are classified.

Table 48-11. Possible Causes for Typical Errors

Error Type	Possible Cause
UR (Unsupported Request)	•Poisoned TLP (EP=1) •No BAR match •MRd length > max read request size

Table continues on the next page...

Table 48-11. Possible Causes for Typical Errors (continued)

UC (Unexpected Completion)	•TAG mismatch. •Requester ID (RID) mismatch.
CPL TimeOut	Remote device hung.
CA (Completion Abort)	ECRC
Malformed TLP (MLF)	Bad TLP header caused by bad link.
Buffer OverFlow	Credit miscalculation by some PCIe device.
Bad DLLP	LCRC

For a full analysis of what error conditions contribute towards an UR or CA status, see Receive Filtering.

NOTE

In many cases, the standard operation may be 'masked' or ignored by setting the corresponding bit in the Symbol Timer Register and Filter Mask Register 1, which take its default value from the DEFAULT_FILTER_MASK_1 configuration parameter.

NOTE

For example, A TLP with the poison bit set (EP=1) is considered an Unsupported Request (UR) only when the UR poison rule mask bit is not set.

48.3.5.5 Error Detection

Built into the core are all mandatory error detections, some optional error detections, and the error report mechanism based on the *PCI Express Specification*.

The core also has an option for the application to turn off the filter rules and perform its own error checking. For more details, see Receive Filtering.

The following general rules apply to all incoming TLPs:

- The core discards all incoming TLPs that have an invalid Type field. This TLP is treated as a 'TLP-ABORT'.
- A locally terminated TLP with ECRC error detected is discarded in store-and-forward mode and an ECRC error reported only when the filter mask CX_FLT_MASK_ECRC_DISCARD bit is not set.
- Filter rules have no affect on received TLP when 'DLLP-ABORT' signal is asserted.

- If a completion of a non-posted request is not received within a completion timeout period, this request will be treated as a completion timeout, and a non-advisory error will be reported. See Advanced Error Reporting (AER) for more details.
- 'DLLP-ABORT' is asserted as a result of one of two conditions:
- a. A data link layer error is detected (e.g. LCRC). A retry from a remote device will occur.
  b. UC or completion with ECRC error is detected. This condition is valid only when the application has configured the core with infinite credits. Because the completion buffer of the core or application has limited resources defined for expected completions, it is necessary to avoid overflowing the completion buffer by unexpected completions. Therefore 'DLLP-ABORT' is asserted to notify the core completion buffer (if completion is in store-forward mode) or application's completion buffer to rewind their buffer pointers when a completion with ECRC error or unexpected completion is detected.
- 'TLP-ABORT' is asserted as a result of one of three conditions:
- Malformed TLP
- UC
- ECRC

The figure below provides a flow chart of the error detections for a packet received from the PCIe wire.

Signals in this figure are internal to the core (except those prefixed with radm_*)

The signals radm_cpl_dllp_abort and radm_cpl_tlp_abort are intended for use with the Completion queue configured in either bypass or cut-through mode so that the core can notify the application of errors detected as the TLP is received.

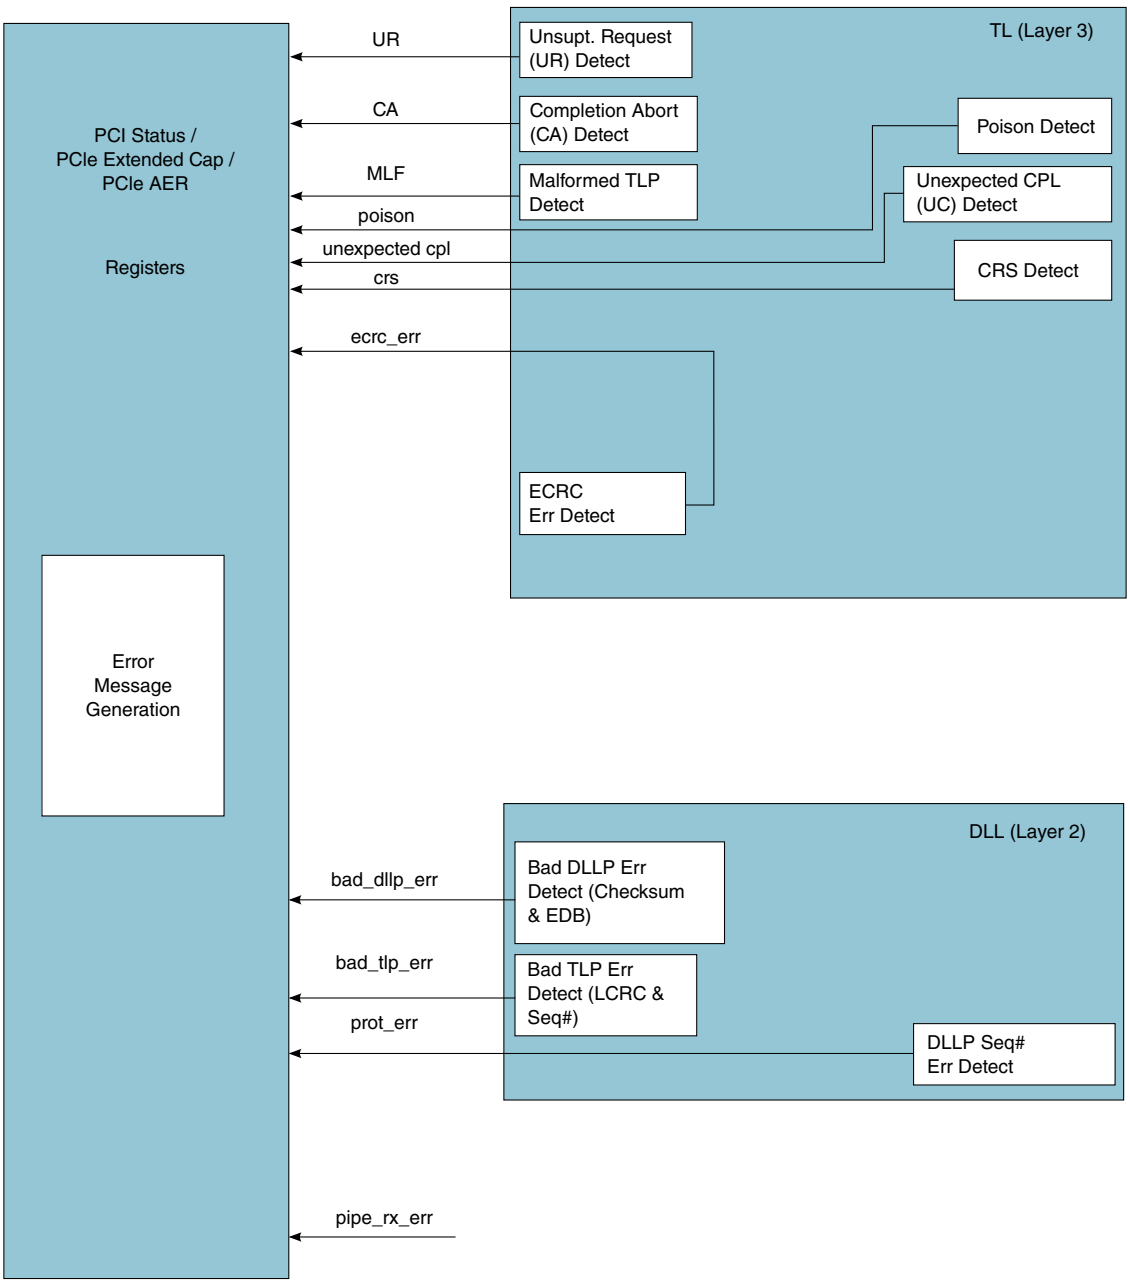

Figure 48-14. Flow Chart of Error Detections

48.3.5.6 Application Error Reporting Interface

The application may optionally generate an Error Message through either of the following methods:

- Directly at the application interface see Message Generation.

- It may instruct the PCI Express core to do so through the 'Application Error Reporting Interface'nsignals app_* .
- You must set the APP_RETURN_ERR_EN configuration parameter to enable the 'Application Error Reporting Interface'.

If you mask detection of Completion timeout errors, through setting the CPL_TIMEOUT_ERR_MASK configuration parameter, then the core will not automatically report Completion timeout errors. The application must check for Completion timeouts and report Completion timeout errors using the app_err_bus input signal.

NOTE

Your application may want to send an error message to the remote link partner if (for example) your application detected an error during the execution of an inbound/received Posted TLP, for example a MWr

48.3.5.7 Handling of General Errors with the AXI Bridge.

PCIe Advanced Error Reporting (AER) is not supported in the AXI bridge.

AER is only supported with respect to the native PCIe core. Errors detected by the AHB/AXI bridge are not reported as part of AER.

48.3.5.8 AXI

The slv_resp_err_map and mstr_resp_err_map bits are tied to 1. The corresponding CPL error will be SLVERR AXI Error Response. The corresponding CPL status error will be UR (Unsupported Request) PCIe CPL Status.

48.3.5.9 Handling of ECRC/LCRC Errors for IO/MEM with the AXI Bridge.

48.3.5.9.1 Link CRC (LCRC) - a correctable Error

When an LCRC error occurs on an inbound packet (request or completion), the core will automatically discard that packet and wait for the remote device to replay the packet.

The native core will signal (via radm_*_dllp_abort) to the AHB/AXI bridge that an LCRC error has occurred.

The AXI bridge will not signal an error to the application but will wait for the replayed packet to arrive.

48.3.5.9.2 End-to-end CRC (ECRC) - an Uncorrectable Non-Fatal Error

REQUESTS

By default, a request TLP with ECRC errors is dropped by the RADM filter in the native core and an Advisory Non-Fatal Error is signalled. For Non Posted (NP) requests, a CPL with CA is generated. See Advisory Non-Fatal Error Messages.

If you set the DEFAULT_TARGET and CX_MASK_UR_CA_4_TRGT1 parameters to 1 (default values are 0), then, a request TLP with ECRC errors will not be dropped but will be forwarded (without any error reporting) to the application on AXI bridge master.

See ECRC Handling for more details.

COMPLETIONS

A completion TLP with ECRC errors is only dropped by the RADM in the native core when CPL queue mode is store-forward and queue architecture is single or multiple queue. However, for the AHB/AXI bridge, when the queue architecture is single or multiple queue, the CPL queue mode is restricted to bypass. Therefore a completion TLP with ECRC errors is always forwarded to the AHB/AXI bridge.

When the AXI/AHB bridge receives a CPL with ECRC errors, it will not transmit it to the application through the AHB/AXI master. Instead, the bridge will wait for the subsequent 'completion timeout' (see Received Completion TLP Processing) generated by the core. It is this timeout that will cause the bridge to issue an ERROR response to the application on each beat of the burst corresponding to the original AHB/AXI request.

48.3.6 Messages

Information found here describes the processing of messages through the core.

NOTE

For a proper understanding of Messages you should be familiar with Message Request Rules of the PCI Express Base Specification.

Similar to MWr, messages (Msg/MsgD) are Posted transactions. The 8-bit 'Message Code' field defines what class of message the TLP is. Some examples of typical message classes are given in the following table.

Table 48-12. Some Message classes based on the Message code

Message Code [7:0]	Message Class	TLP Type	Note
0001_xxxx	Power Management	Msg	
0010_0xxx	Legacy PCI Interrupt	Msg	Assert/deassert for each of INT A/B/C/D.
0011_00xx	Error Signalling	Msg	ERR_CORR, ERR_NONFATAL, ERR_FATAL are encoded using 30h, 31h, 33h.
0111_11xx	Vendor Defined	Msg / MsgD	
Other classes (used by PCIe core) include Locked Transaction, Slot Power Limit.			

NOTE

Message Signalled Interrupts (MSI/MSI-X) are not messages (Msg/MsgD) but MWr TLPs. See Interrupts for more details.

48.3.6.1 Message Generation

Messages that are transmitted by the PCI Express core can potentially be derived from the following eight sources. Referring to the circled numbers in the following diagrams, outbound messages can be created either by:

the core automatically as follows:

- 'Power Management' messages.
- 'Error Signalling' messages.

or

the customer application as follows:

- Direct supply of message TLPs at AXI bridge master. An internal or external internal address translation unit (ATU) can convert IO/MEM TLPs to MSG TLPs.
- 'Locked Transaction' messages through the 'SII Message' interface [RC mode]. 'Legacy PCI Interrupt' messages through the 'SII Interrupt' interface.
- 'Error Signalling' messages through the 'SII Transmit Control' interface (app_err* I/O).

or

the host/client software as follows [RC mode]:

- Triggering the sending of 'Slot Power Limit' messages by writing to the Slot Capabilities Register.

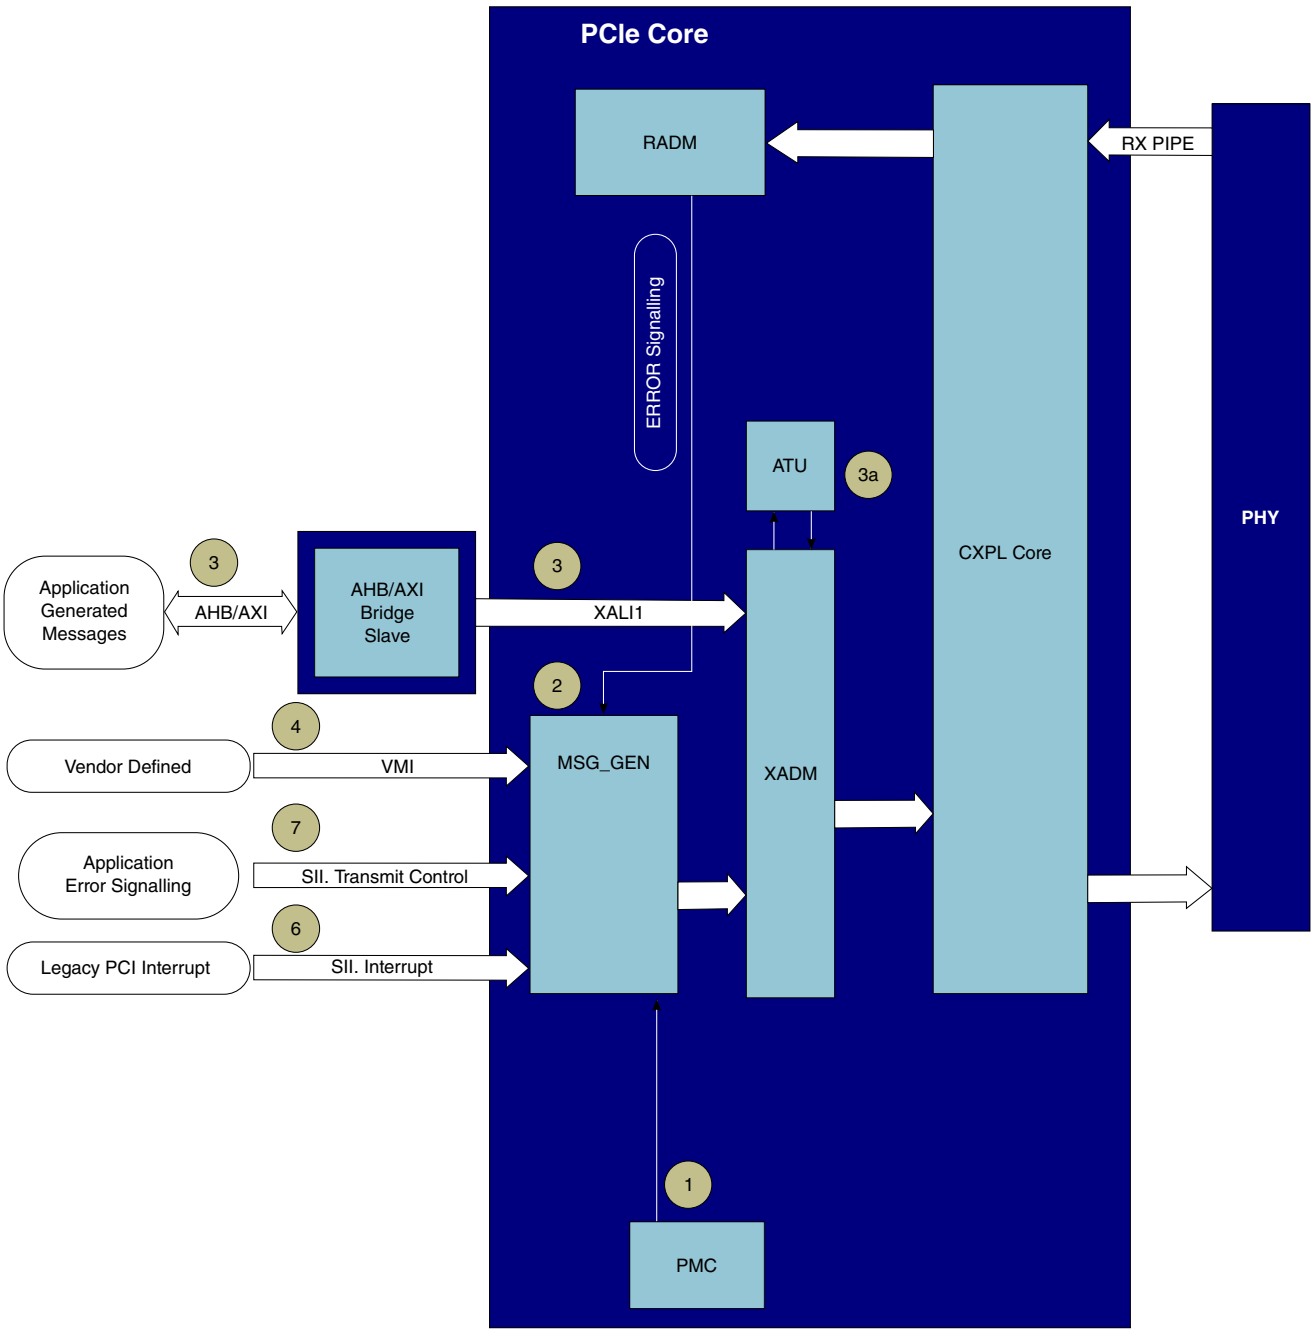

Figure 48-15. Message Transmission: EP mode

See Terms and Abbreviations for definitions of acronyms used for block and interface names.

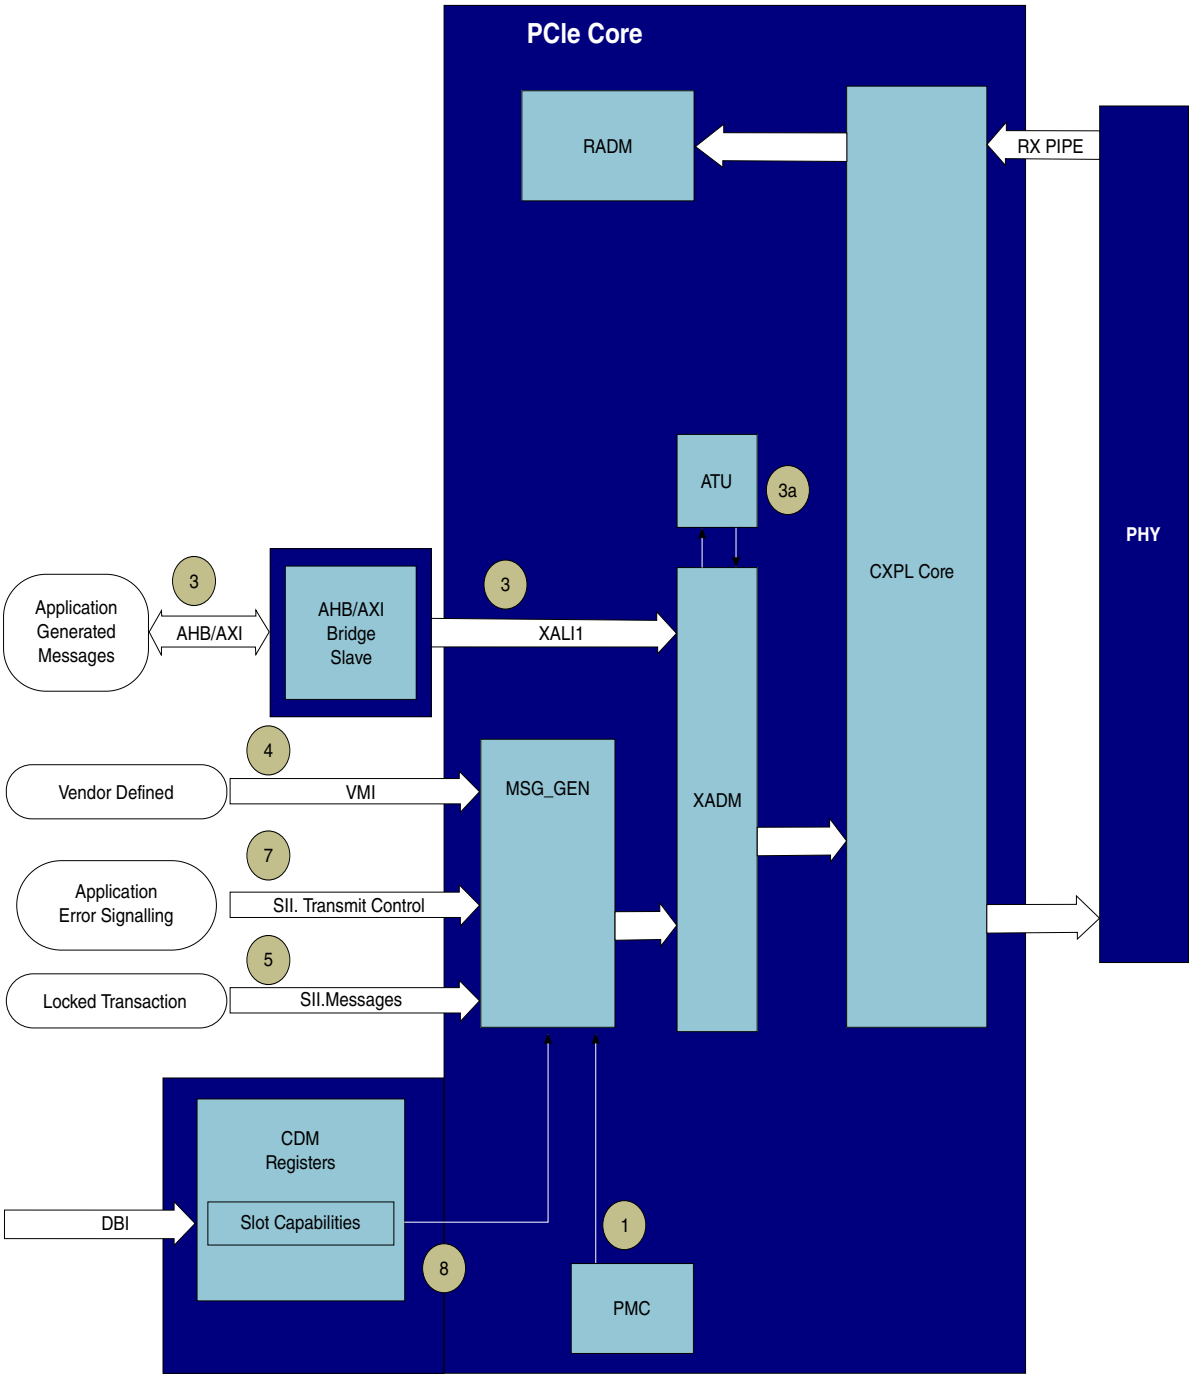

Figure 48-16. Message Transmission: RC mode

Table 48-13. Message Transmission. The 'Index' refers to the numbers in the previous diagrams

Index	Message Source (Type)	EP Mode	RC Mode

Table continues on the next page...

Table 48-13. Message Transmission. The 'Index' refers to the numbers in the previous diagrams (continued)

1	Power Management controller in the core (Msg).	PM_PME[1]	PME_Turn_Off[2] See Power Management.
2	Error Signalling inside the core (Msg).	COR_ERR / ERR_NONFATAL / ERR_FATAL. See Error Handling for more details.	n/a
3	Direct Supply of any class of Message (Msg/MsgD).	XALI0/1/2 or AHB/AXI See Application Msg/MsgD Programming Examples for details on how to generate a message at the XALI0/1/2 (or AHB/AXI) interfaces.	
3a	Indirect Supply of any class of Message (Msg/ MsgD).	See Outbound iATU Operation for more details on generating Msg/MsgD from MWr/IOWr using an internal or external address translation unit (ATU).	
5	Locked Transaction (Msg).	n/a	Unlock Message, triggered by Root Complex application logic via the app_unlock_msg pin.
6	Legacy PCI Interrupt (Msg).	'SII Interrupt' pins sys_int and dp_intx (see PCI Legacy Interrupt).	n/a
7	Error Signalling from the application (Msg).	The core generates Error Signalling Messages in response to application requests on the SII app_err* I/O . It is also possible to generate Error Messages via the client interfaces. See items 3 and 3a in this table.	
8	Slot Power Limit (Msg).	n/a	Set_Slot_Power_Limit Support Message, triggered by writing to the Slot Capabilities Register via the DBI.

1. Triggered by your EP application through the outband_pwrup_cmd or apps_pm_xmt_pme pin.

2. Triggered by your RC application through the apps_pm_xmt_turnoff pin.

3. MsgD not possible on VMI. See Vendor Defined Message (VDM) Generation.

48.3.6.1.1 Vendor Defined Message (VDM) Generation

VDMs can be generated by your application using any of the following methods (numbered 4, 3 and 3a in Table 48-13).

- Direct supply of IO/MEM TLPs AXI bridge master to be converted to VDM by either of the following.
- The internal Address Translation Unit (iATU) can convert IO/MEM TLPs to VDM TLPs.

48.3.6.1.1.1 Application Msg/MsgD Programming Examples

The tables found here enumerate the different ways your application can generate Msg and MsgD TLPs.

NOTE

xATU = "External Address Translation Unit" and iATU = "Internal Address Translation Unit (iATU)".

Table 48-14. Msg (message without payload) Generation Methods

Application Interface	Description	Application I/O Signals
AXI	Direct Supply using a Msg transaction.	slv_awmisc_info[4:0]='MSG" slv_wstrb[3:0]='0000'
	Indirect Supply (iATU) using a MWr[1] transaction. The iATU needs to be configured to translate MWr to Msg TLPs.	slv_awmisc_info[4:0]='MEM' slv_wstrb[3:0]='0000'

1. Or IOWr

NOTE

xATU = "External Address Translation" and iATU = "Internal Address Translation (iATU)".

Table 48-15. MsgD (Vendor Specific Message with payload) Generation Methods

Application Interface	Description	Application I/O Signals
AXI	Direct supply using an MsgD transaction.	slv_amisc_info[4:0]='MSG'
	Indirect Supply (xATU) using a MWr transaction.	slv_amisc_info[4:0]='MEM' xtranslated_enable =1 xtranslated_addr_in_d[8]=1 xtranslated_addr_in_d[7:0]=Message Code xtranslated_type_in_d = 10xxx
	Indirect Supply (iATU) using a MWr[1] transaction. The iATU needs to be configured to translate MWr to MsgD TLPs.	slv_amisc_info[4:0]='MEM'

1. Or IOWr

48.3.6.1.2 AHB/AXI Message Address and Size Limitations

Limitations existing in the current implementation of the AHB/AXI bridge module can be found here.

NOTE

- Vendor Messages must not be decomposed in the inbound or outbound direction.
- You must ensure that Vendor Defined Messages generated by your application or remote link partner, do not trigger decomposition as described in AXI Decomposition Rules.

Table 48-16. Processing of Inbound Messages when AHB/AXI and PCIe Core Address Widths are different

AHB/AXI Address Bus Width MASTER_BUS_ADDR_WIDTH	PCIe Core Address Bus Width FLT_Q_ADDR_WIDTH	Notes
32	64	The upper 32 bits of the data field (bytes[1] 8-11) are not forwarded by the bridge master.
64	32	The upper 32 bits of data field (bytes 8-11) will be forced to '0'.

48.3.6.2 Message Reception

The PCI Express core can receive the following types of messages. The index in the first column refers to the circled numbers in the following diagrams.

.

Table 48-17. Message Reception. The 'Index' refers to the numbers in the following diagrams

Index	Message Source (Type)	EP Mode	RC Mode
1	Power Management (Msg).	PME_Turn_Off See Power Management.	PM_PME PME_TO_Ack
1a	Slot Power Limit (Msg).	Set_Slot_Power_Limit Support Message.	n/a
2	Error Signalling from downstream component (Msg).	n/a	COR_ERR / ERR_NONFATAL / ERR_FATAL.
3	Vendor Defined (Msg/MsgD).		
4	Locked Transaction (Msg).	Unlock Message.	n/a
5	Legacy PCI Interrupts from downstream devices (Msg).	n/a	See PCI Legacy Interrupt.

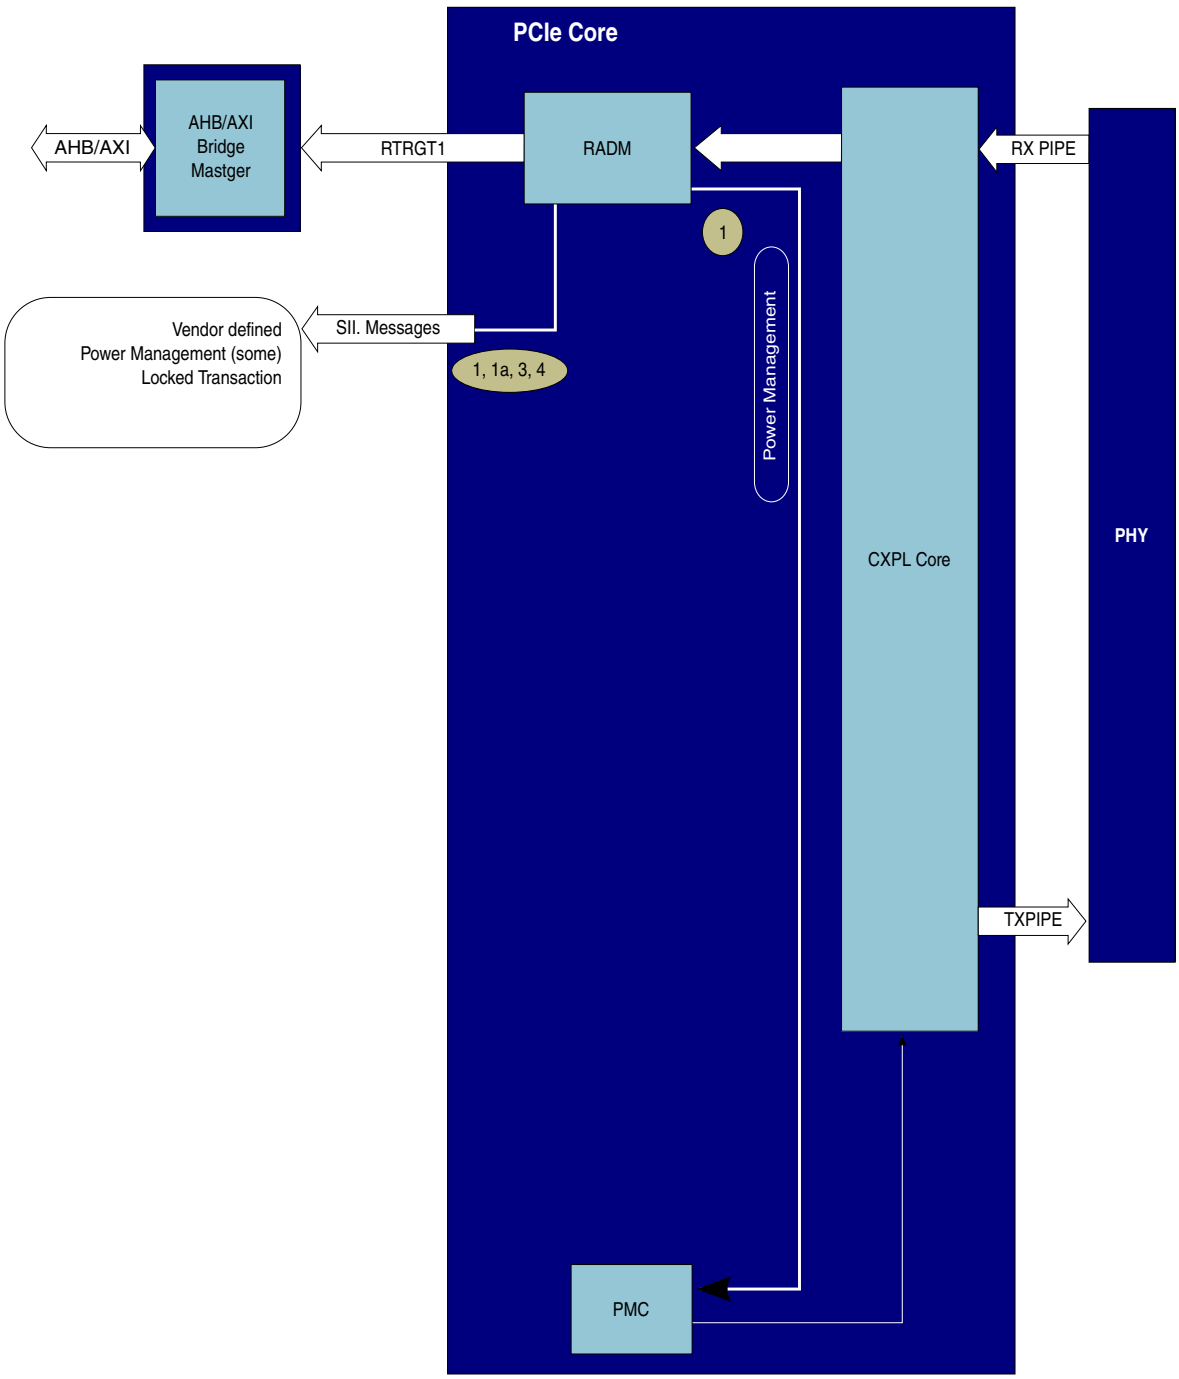

Figure 48-17. Message Reception: EP mode

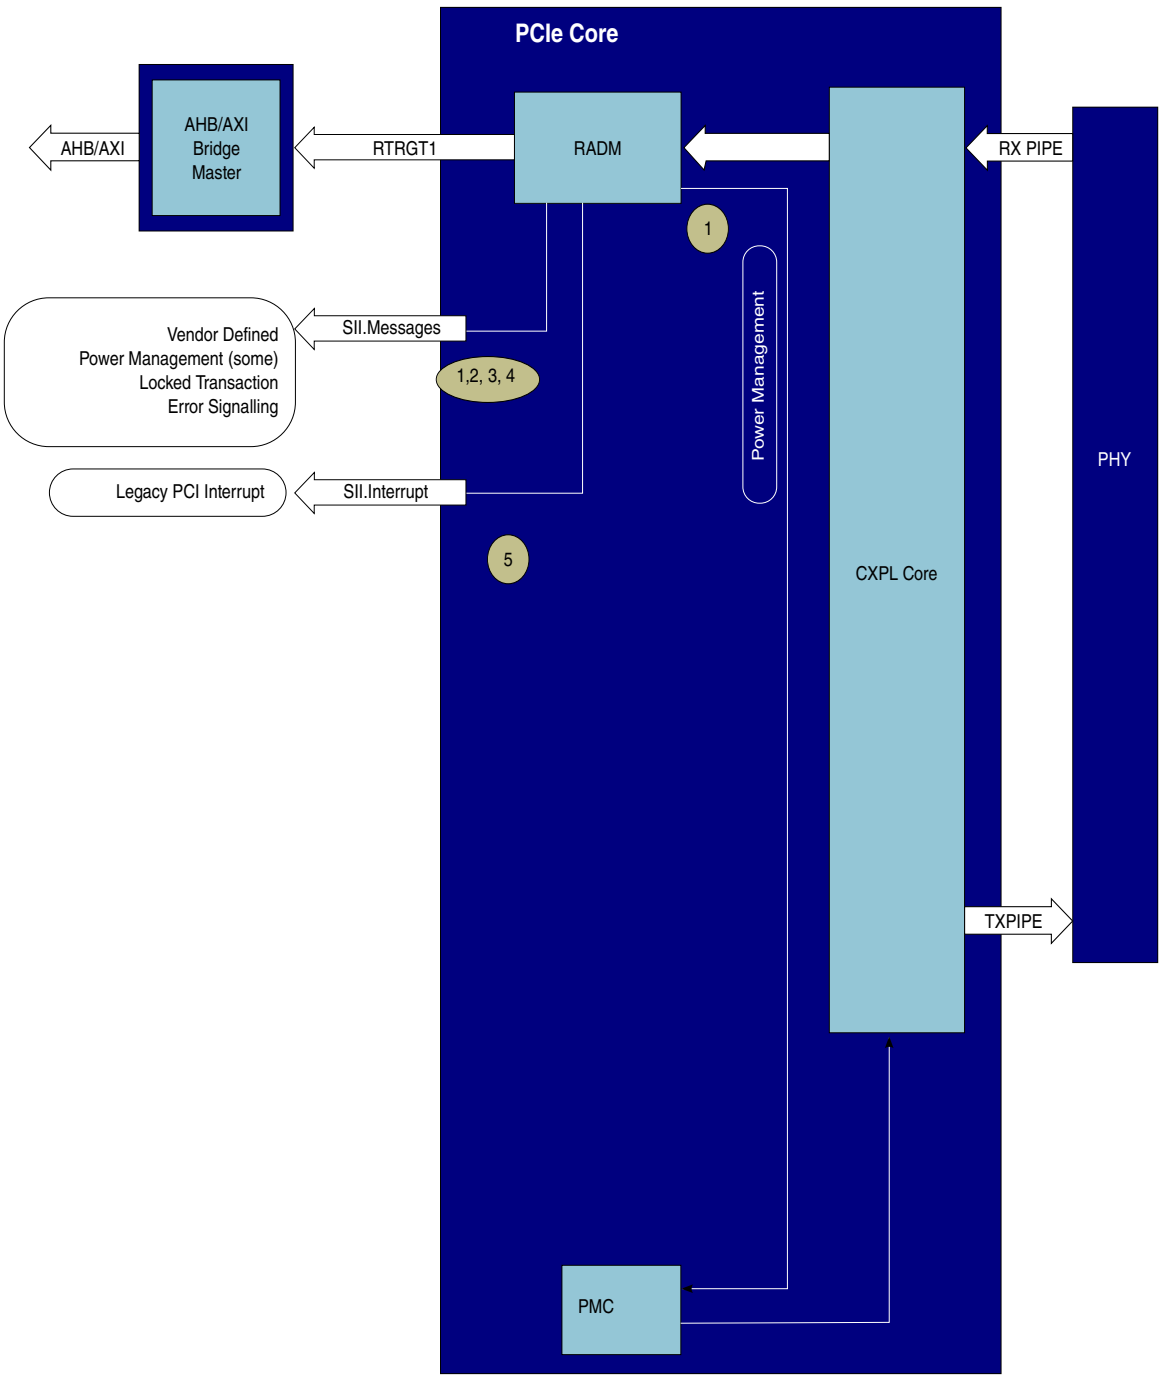

Figure 48-18. Message Reception: RC mode

See Terms and Abbreviations for definitions of acronyms used for block and interface names.

48.3.6.2.1 Message Reception IO Interfaces

The RADM filter provides a Message interface - that is grouped as part of the System Information Interface (SII) - to handle the Message TLPs received from the upstream component. The RADM filter processes the Message and decodes the header before sending it to the application logic on the SII.

48.3.6.2.2 Routing of Received Messages to SII and optionally to Application

The RADM filter processes *every* received message and decodes the header before sending it to the application logic on the System Information Interface (SII).

In addition, power management messages are processed by the PCIe core Power Management Controller (PMC).

By default, all received messages are dropped[1] (serviced internally) and *not* passed to the application on AXI bridge master.

To have all decoded messages *also* sent to the application interface (AXI bridge master), the register fields must be set to '1'. These registers allow you to override any decisions (regarding MSG routing) made at configuration time by the FLT_DROP_MSG, DEFAULT_FILTER_MASK_1 and DEFAULT_FILTER_MASK_2 configuration parameters .

Table 48-18. Controlling the Routing of Received Messages

Register	Bit	Function	Default Value
Filter Mask Register 1	29	Mask the dropping of Non-Vendor Messages 0: Drop 1: Do not drop	DEFAULT_FILTER_MASK_1[13] = ! FLT_DROP_MSG = 0
Filter Mask Register 2	0	Mask the dropping of Vendor Type 0 Messages 0: Drop[1] 1: Do not drop	DEFAULT_FILTER_MASK_2[0] = 0
Filter Mask Register 2	1	Mask the dropping of Vendor Type 1Messages 0: Drop 1: Do not drop	DEFAULT_FILTER_MASK_2[1] = 0

1. Vendor TYPE0 Messages are dropped with UR error reporting.

For the masking (of the dropping) of Vendor messages, it is not possible to differentiate between 'Vendor Message without Payload (Msg)' and 'Vendor Message with Payload (MsgD)'.

Full details of the Filter Mask Registers are at Symbol Timer Register and Filter Mask Register 1and Filter Mask Register 2.

When a MSG request is filtered with UR/CA/CRS status, the TLP is always dropped. Only MSG requests filtered with SC status, can potentially be forwarded to the application on AXI bridge master.

48.3.6.2.3 Accessing Header and Payload Fields of Received Messages

Format of Received Messages on the Application RTRGT1 Interface

In addition to normal TLP header information, the last two DWORDS of the message header (bytes[1] 8-15) are presented on radm_trgt1_addr[FLT_Q_ADDR_WIDTH-1:0] when radm_trgt1_hv is asserted.

Format of Received Messages on the Application AHB/AXI Master Interface

In addition to normal TLP header information, the last two DWORDS of the message header (bytes[1] 8-15) are presented on the master address bus as follows:

- AHB/AXI address[31:0] = 4th DWORD = bytes 12-15
- AHB/AXI address[63:32] = 3rd DWORD = bytes 8-11

The TYPE field of mstr_awmisc_info/mstr_req_misc_info indicates the type of message TLP received. The remote link partner should not use the last DWORD of a Msg/MsgD header (bytes[1] 12-15). If the last DWORD must be used, then the two lower bits (byte15) must be always set to 00b. If these two bits are not zero, then the AHB/AXI master interface (when it forwards the message packet to the AHB/AXI fabric) will initiate a burst of 8-bit or 16-bit transactions.

Messages Without Payload Restriction on AHB

Messages without Payload (Msg) cannot be forwarded to the AHB bridge module master interface, as there is no concept of 'write strobes' in AHB to support null/empty write packets. Therefore it is only possible to access (parts of) the received Msg (message without payload) over the SII.

Format of Received Messages on the SII

Not all of the message TLP fields are sent to the SII. For some messages, only an indication that it has been received is signalled. For Vendor Defined messages (Msg or MsgD), the 3rd DWORD (bytes[1] 8-11) is sent to radm_msg_payload[31:0] but the fourth DWORD (bytes 12-15) is not presented at all. Furthermore, for Vendor Defined messages with payload (MsgD), the payload is not presented on SII.

Therefore, to access this missing information (if required), it is necessary to unmask the dropping[2] of Vendor Messages and have them sent to the application interface (AXI bridge master) in order to access the payload. This can be problematic for AHB as it is not possible to differentiate between 'Vendor Message without Payload (Msg)' and 'Vendor Message with Payload (MsgD)' for the masking (of the dropping) of Vendor messages. To avoid, this problem, program the remote link partner to not send Vendor Defined messages without payload (Msg), to an AHB connected end point.

48.3.7 Interrupts

Information found here describes the processing of interrupts through the core.

48.3.7.1 Interrupts Overview

The application logic in a PCI Express Endpoint may use one of three methods to signal an interrupt:

PCI legacy interrupt

PCI includes up to four virtual interrupt wires, referred to as INTA, INTB, INTC, and INTD. These wires are shared by all the PCI devices in the system. PCI Express emulates this capability by providing Assert_INTx and Deassert_INTx Message packets sent through the PCI Express serial Link.

MSI

A PCI Express Endpoint may signal an MSI by sending a standard PCI Express Posted Write packet towards the Root Port. The packet must contain a specific address and one of up to 32 data values. The varying data values, and the address value provide more detailed identification of interrupt events than legacy interrupts.

The PCI Express Cores support optional MSI per-vector masking (PVM).

MSI-X

An MSI-X interrupt is identical to an MSI, except that an Endpoint may use one of up to 2048 address and data pairs in the MSI-X Posted Write packet. Endpoints with MSI-X capability also include application logic to mask and hold pending interrupts, as well as a memory table for the address and data pairs. The large number of address values available to each Endpoint allows MSI-X Messages to be routed to different interrupt consumers in a system, as compared to the single address available to MSI packets.

Root Ports cannot send MSI-X packets. In complex systems, MSI-X packets could be routed to devices other than the RC, including other Endpoints, based on the multiple address/data pairs available.

Support of legacy interrupts and/or MSI/MSI-X may be required for backward compatibility.You may configure your core and application logic to support all three types of interrupts. However, you may only use one of these capabilities at a time. When host software clears the MSI Enable bit, you may only use legacy interrupts. When host software sets the MSI Enable bit, you may only use MSI. If if host software enables MSI or MSI-X, legacy interrupts are automatically disabled. Functionality is undefined if both MSI and MSI-X are enabled.

48.3.7.1.1 PCI Legacy Interrupt

NOTE

Legacy Interrupt delivery are signalled using special Msg TLPs. For more details see Messages.

The PCI Express Endpoint Core provides an input pin (sys_int[NF-1:0]) per function, so that application logic can assert or deassert a legacy interrupt.

The Core automatically maps assertion/de- assertion edges on the input pin to PCI Express Assert or Deassert messages. Root Ports decode received Assert/Deassert messages into pulses. Refer to System Information Interface (SII) for additional information.

Multifunction Support

A single-function Endpoint always uses INTA. However in a multi-function Endpoint, you may choose which virtual interrupt is used for each function by setting the initial value of the Interrupt Pin configuration register. In a multi-function Endpoint, each function has its own interrupt input pin (sys_int[NF-1:0]). Each function's Interrupt Pin register determines which legacy interrupt Message the function uses (INTA, INTB, INTC, or INTD).

Ordering Considerations

You may wish to guarantee that a legacy interrupt Message is sent after a data packet. In that case, do not assert the interrupt input pin until after the data packet's header is accepted by the core's transmit client interface.

In a complex PCI Express system, which include Switches and/or multiple Virtual Channels, you cannot guarantee that the interrupt Message will arrive after a data packet, unless the data packet uses the same Traffic Class as the legacy interrupt packet (Traffic Class 0).

Deassertion of Interrupts

The application needs to deassert the virtual interrupt inputs if system software has disabled interrupts or if the PCI Express link has been placed in a low power state.

The Core does automatically send a Deassert Interrupt Message when software disables interrupts. However, the application must eventually deassert the virtual interrupt before it can send a new interrupt because the Core requires a rising edge on the virtual interrupt signal to generate a new Assert Interrupt Message.

The Core does not automatically send a Deassert Interrupt Message when the power state changes.

48.3.7.1.2 MSI

Message Signalled Interrupts (MSI) are not messages (Msg/MsgD) but Memory Write (MWr) TLPs. They are indistinguishable from normal MWr's apart from the target address used in conjunction with the MSI Capability Structure. PVM (Per Vector Masking) is supported with MSI.

The PCI Express Core automatically builds an MSI packet for your application (if MSI is enabled) whenever requested by your application logic.

A simple handshake is required. The MSI interface is used only in the DM core in EP mode.

The Core informs the application logic whether MSI interrupts are enabled, and how many MSI data vectors have been allocated by system software.

Before performing the handshake, application logic must assert Traffic Class, and MSI vector information on the Core input pins. The Core inserts the Traffic Class into the MSI packet. It also merges the MSI vector number into the MSI packet data field.

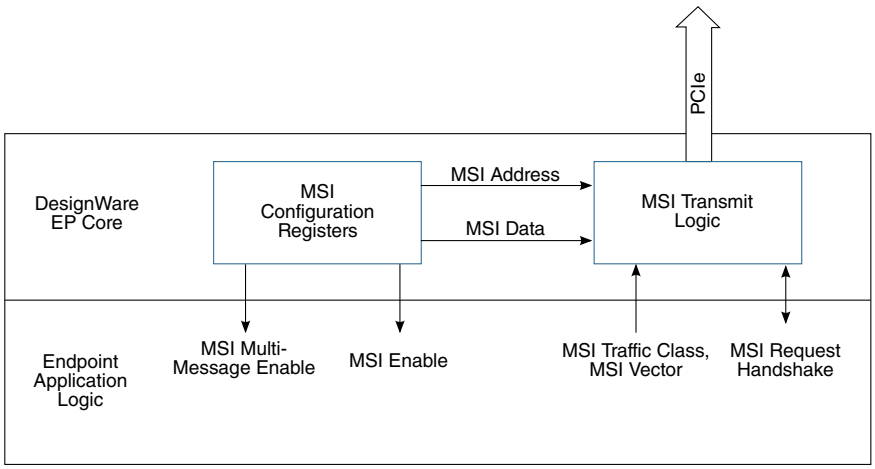

Figure 48-19. MSI Message Passing

When an Endpoint sends an MSI Message, the Message packet is routed by address in the same way as any other PCIe Posted Write packet. In most systems, these packets will be routed to the Root Port and sent to Root Port application logic. The Root Port application logic recognizes the Posted Write packet by its MSI address and handles the interrupt in hardware or software. The data field is also available in the packet to further define the interrupt.

Multifunction Support

Each function in a multi-function device has its own configuration space, and therefore, its own MSI output controls. A multi-function core adds a function number to the MSI inputs shown in the following figure.

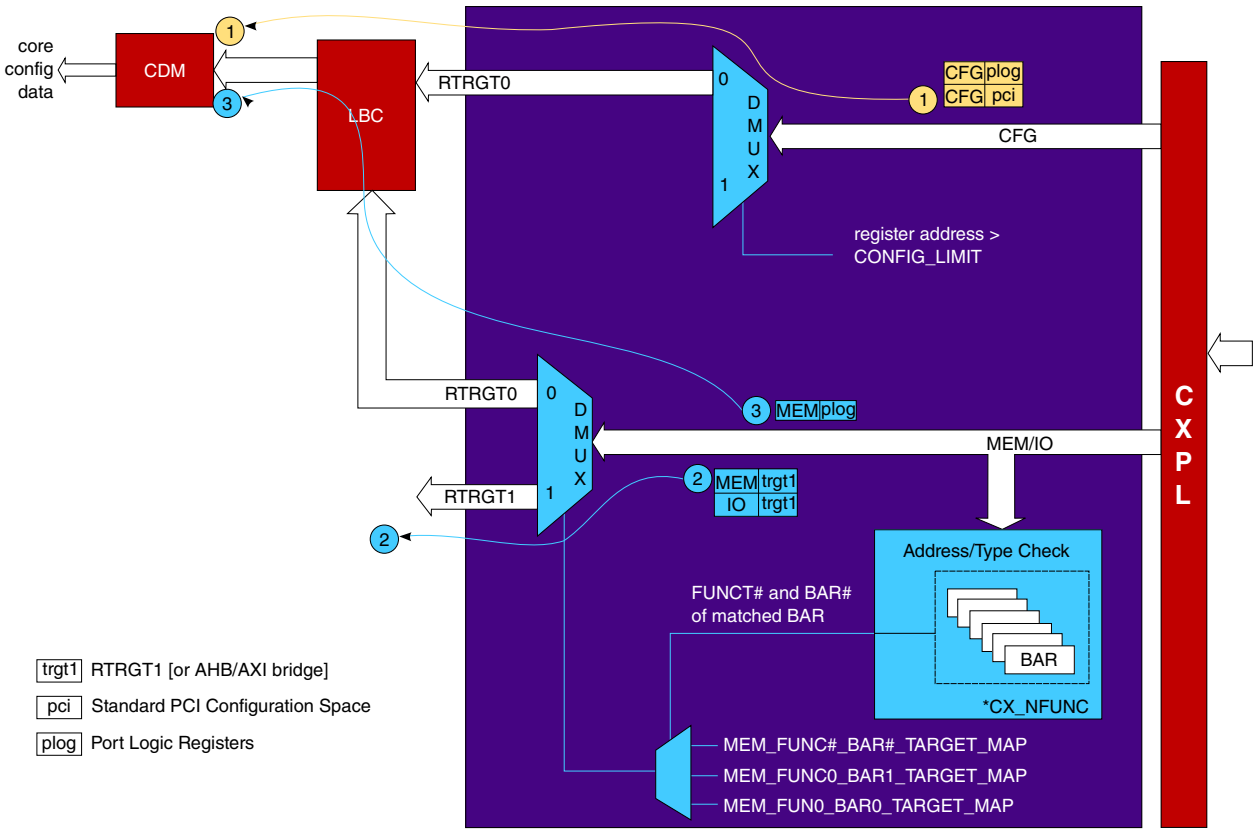

Figure 48-20. Typical use model

Ordering Considerations

You may wish to guarantee that an MSI is sent after a data packet. By setting the MSI packet's Traffic Class to the same value as an earlier data packet, you can guarantee that the MSI packet will always arrive at its destination after the data packet.

NOTE

The PCIe core sets the first byte enable (FBE) to 4'b1111 when it generates an MSI request, even though only the first two bytes of the payload are strictly valid/needed.

48.3.7.1.3 MSI-X

Message Signalled Interrupts (MSI-X) are not messages (Msg/MsgD) but Memory Write (MWr) TLPs. They are indistinguishable from normal MWr's apart from the target address used in conjunction with the MSI-X Capability Structure.

The PCI Express Core automatically builds an MSI packet for your application (if MSI-X is enabled) whenever requested by your application logic.

A simple handshake is required. The MSI-X interface is used only in the DM core in EP mode.

The following MSI interface signals are also used for MSI-X, depending on whether MSI or MSI-X is enabled: ven_msi_req, ven_msi_func_num, ven_msi_tc, and ven_msi_grant.

The address and data fields for MSI-X packets are defined in an MSI-X table located in the Endpoint's application logic, as shown in the figure below. Each entry in the table corresponds to an MSI-X packet that the application may send.

Each MSI-X table entry also includes a mask bit for that interrupt. An additional table, the pending bit array (PBA), includes a pending bit for each MSI-X table entry.

Host software sets and clears mask bits. If an interrupt's mask bit is set when the application wishes to send that MSI-X packet, the application must, instead, set the corresponding entry in the PBA.

Application logic monitors pending bits. If the corresponding mask bit is cleared, then the application sends the corresponding MSI-X packet, and clears the pending bit.

In addition, the MSI-X configuration registers in the Core include:

- Pointers to the function's MSI-X table and PBA
- Length of the function's MSI-X table
- An enable bit for MSI-X for that function
- A global mask for MSI-X

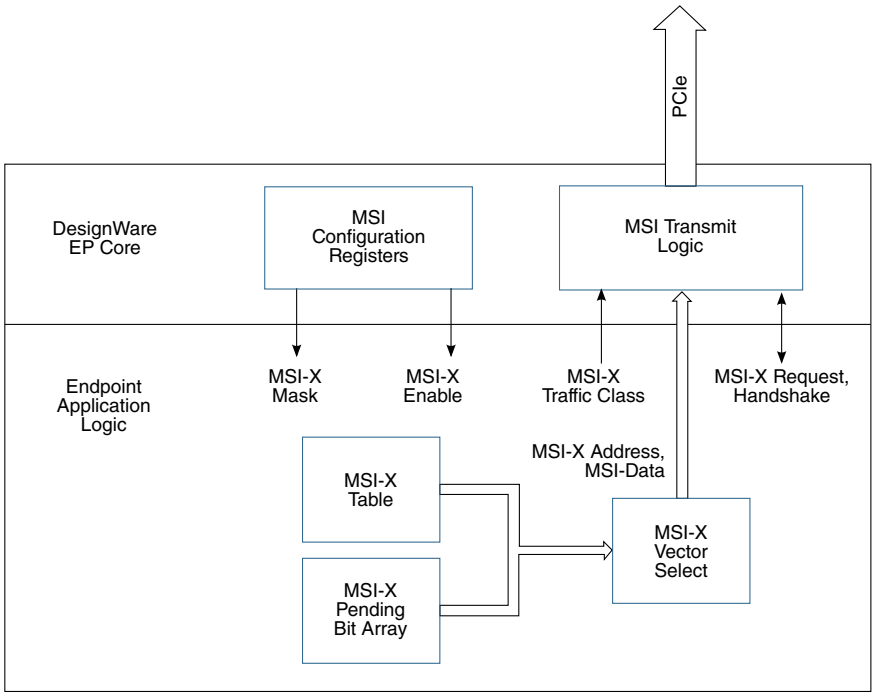

Figure 48-21. MSI-X Message Passing

Large MSI-X Tables

The MSI-X specification is written such that large MSI-X tables and PBAs may be implemented in compiled memories. However, if the host clears the function's global MSI-X mask, a search of the entire 2048 entry PBA might be necessary.

Also, in a large memory array like this, there would be no ìmemoryî of the order in which the pending bits were set. This is not an MSI-X requirement, but might be required by some systems.

48.3.7.2 Interrupts (EP Mode)

In EP mode, the core supports the Legacy PCI INTx compatible interrupt emulation mechanism, the Message Signaled Interrupts (MSI).

A function can use the Legacy PCI INTx mechanism. Different functions of the same device can use different mechanisms. For example, function 0 can use INTA while function 1 uses MSI.

Legacy PCI INTx Support

The core generates two Messages, ASSERT_INTX and DEASSERT_INTX, in response to assertion and the deassertion of the sys_int input. The Interrupt Pin register for each function determines whether the function uses INTA, INTB, INTC, or INTD.

In a single-function configuration, the core uses only INTA. An input signal, sys_int, is provided for the application to notify the core that an interrupt message should be sent. The sys_int signal is level-sensitive on a per-function basis. The rising edge transition of this signal triggers an interrupt assert message. The falling edge transition of this signal triggers an interrupt deassert message.

Message Signaled Interrupt (MSI) Support

MSI support is required for PCI Express devices. MSI-capable devices deliver interrupts by performing Memory Write transactions. The MSI is requested by application logic through the MSI interface; the core then generates the corresponding Memory Write.

48.3.7.3 Interrupts (RC Mode)

In RC mode, the core accepts ASSERT_INTX and DEASSERT_INTX Messages from the downstream component and provides the decoded output signals on the SII (for example, radm_inta_asserted and radm_inta_deasserted).

For interrupts the downstream component transmits through the MSI-X mechanism, the core passes the received Memory Write to the application on the RTRGT1 interface.

PCI Express Hot-Plug Logic Interrupt and Wakeup

In RC mode, the Hot-Plug logic supports generation of Hot-Plug interrupts on the following Hot-Plug events:

- Power Fault Detected
- MRL Sensor Changed
- Presence Detect Changed
- Command Completed
- Attention Button Pressed
- Electromechanical Interlock Status Changed
- Data Link Layer State Changed

When MSI or MSI-X mode is enabled, the core notifies the RC application of Hot-Plug events using the hp_msi output. When INTx interrupt mode is enabled, the core notifies the application of Hot-Plug events using the hp_int output.

If PME is enabled, the The Hot-Plug logic generates a Hot-Plug wake-up signal on hp_pme, triggered by the above Hot-Plug events. The RC Core does not check if the PM state is D1, D2, OR $D3_{HOT}$. It is up to the application to check the value on pm_dstate to make sure the device is in D1, D2, OR $D3_{HOT}$ upon receiving of hp_pme notification.

48.3.7.4 MSI Generation in the AXI Bridge

The standard AXI bridge simply sends MSI requests in the same manner as a memory write.

The method to send a MSI request is to have theAXI bridge send MSI requests in the same manner as a regular memory write. It is the application's responsibility to form the MSI request based on the native PCIe core's configuration. The native PCIe core CDM block contains the MSI address, enable, etc.

The application must obtain the MSI information (cfg_msi_*) from reading the MSI capability registers inthe CDM through the DBI interface, and then form the MSI request to present onto the AXI bridge slave interface.

This method should be used by an application that wants to preserve the order of Posted transfers (MemWr) requested before an MSI request.

The AXI bridge simply sends MSI requests in the same manner as a memory write. To send an MSI to the PCIe link from the AXI bridge, the application presents the MSI address and data onto the AXI slave write channel.

48.3.7.5 MSI Reception in the AHB/AXI Bridge

The standard AHB/AXI bridge receives MSI requests in the same manner as a memory write.

It cannot and does not distinguish between MSI and memory requests. The termination of an MSI request (in RC mode) must be done by the application or by using the optional MSI Controller described next.

48.3.7.5.1 AHB/AXI MSI Controller (Optional in RC mode)

The bridge provides an optional programmable MSI controller to detect and terminate inbound MSI requests in the bridge for RC and DM (RC mode) products. It is enabled by setting the CX_MSI_CTRL_ENABLE) configuration parameter.

Rather than propagating MSI MWr TLPs onto the AHB/AXI bus via the Master interface; the MSI packets are captured and terminated in the AHB/AXI Bridge and an interrupt is signaled.

The MSI Controller is programmed with an address that will be used as the system MSI address. If an inbound (received) MWr request is passed to the AHB/AXI Bridge and matches the specified MSI address as well as the conditions specified for an MSI Memory Write request, then an MSI interrupt is detected. When this Memory Write Request is about to be driven onto the AHB/AXI bridge Master Interface - it is quashed and never appears on the AHB/AXI bus.

The MSI Controller decodes the MSI MWr data payload to determine which End Point device (EP) sent the MSI and which interrupt vector it corresponds to. When a valid interrupt has been decoded, the msi_ctrl_int output is asserted. This output remains asserted when any MSI interrupt is pending. It is only deasserted when there is no MSI interrupt pending.

Features:

- MSI Interrupt Controller only enabled in RC core and DM core in RC mode based on the
- device_type input to DM. It is inactive in EP mode.
- The MSI Interrupt controller will provide support for up to eight EPs. Each supported EP will have a set of Interrupt Enable, Interrupt Mask and Interrupt Status registers.
- A maximum of 32 interrupts are supported per EP.

MSI Request Detection Criteria:

An MSI Interrupt Request is defined to occur when a Memory Write TLP that satisfies the following conditions is received by the core:

- Header Attributes bits are zero. No Snoop (NS) and Relaxed Ordering (RO) must be zero.
- Length field is 0x01 to indicate payload of one DWORD.
- First Byte Enable must be such that it is enabling the first 2 bytes (16-bits) of the payload.
- Last Byte Enable is 4'b0000.
- TLP address corresponds to system's chosen MSI Address as programmed in the MSI Controller Address Register. This register is not the MSI Lower 32 Bits Address Register which is part of the PCI Express MSI Capability Register structure.

In addition to the conditions outlined above, the Memory Write Request must also pass the receive filtering rules as outlined in Receive Filtering to be recognized as a valid MSI Interrupt Request. For example, Poisoned Bit not set in TLP header, ECRC check passed.

48.3.7.5.2 Programming and Usage Model

- The host CPU configures MSI capabilities of all Endpoints (EP) via the local DBI bus (or[1] via Config requests from the remote link partner).
- The MSI data register (MSI Data Register which is part of the PCI Express MSI Capability Register structure) of each EP is programmed as follows to allow the MSI Interrupt Controller to decode the interrupt source.

Table 48-19. MSI Data Register Programming for Use with AHB/AXI MSI Interrupt Controller

15:8	7:5	4:0
Not Used	EP Number •Allows each EP to be identified within the system, •For example, EP#5 is programmed with 3'b101.	Interrupt Vector Number •Identifies the interrupt source within each EP. •Programmed to 5'b00000. •Set by MSI generation logic to identify each interrupt source in real time. •Supports up to 32 Vectors.

- The MSI address register (MSI Lower 32 Bits Address Register which is part of the PCI Express MSI Capability Register structure) of each EP is programmed with the same message address.
- The host CPU configures the MSI Interrupt Controller via the local DBI bus (or via Config requests from the remote link partner).
- The common MSI Address that was used for the EPs is programmed into MSI Controller Address Register in the Interrupt Controller (MSI Controller Address Register).
- The Host CPU reads the MSI capabilities of each EP to determine the number of vectors enabled in each EP and uses this information to program the Interrupt Enable registers in the MSI Interrupt Controller. The Interrupt Enable register allows up to 32 MSI Interrupt Vectors to be enabled within the MSI Interrupt Controller for a given EP. It is the responsibility of the host CPU to read the contents of the "Multiple Message Enable" field in an EP's MSI capability structure and program that EP's Interrupt Enable register in the Interrupt Controller appropriately. For example, if Multiple Message Enable is 3'b100 for Endpoint N, which corresponds to 16 enabled Interrupt Vectors, then Interrupt Enable Register N in the Interrupt Controller should be programmed with 0x0000FFFF by the host CPU.

The MSI Interrupt Controller in your core is active and terminates all received MSI MemWr unless you deactivate it.

NOTE

The MSI Interrupt Controller is deactivated when:

- The core is not in RC mode (applies to DM product only). That is, device_type[3:0] is not 4'b0100.
- All of the eight Interrupt Enable Registers have a value of 0x0.

PROCESSING OF DETECTED INTERRUPTS

The MSI Controller decodes the MSI MWr data payload to determine which End Point device (EP) sent the MSI and which interrupt vector it corresponds to.

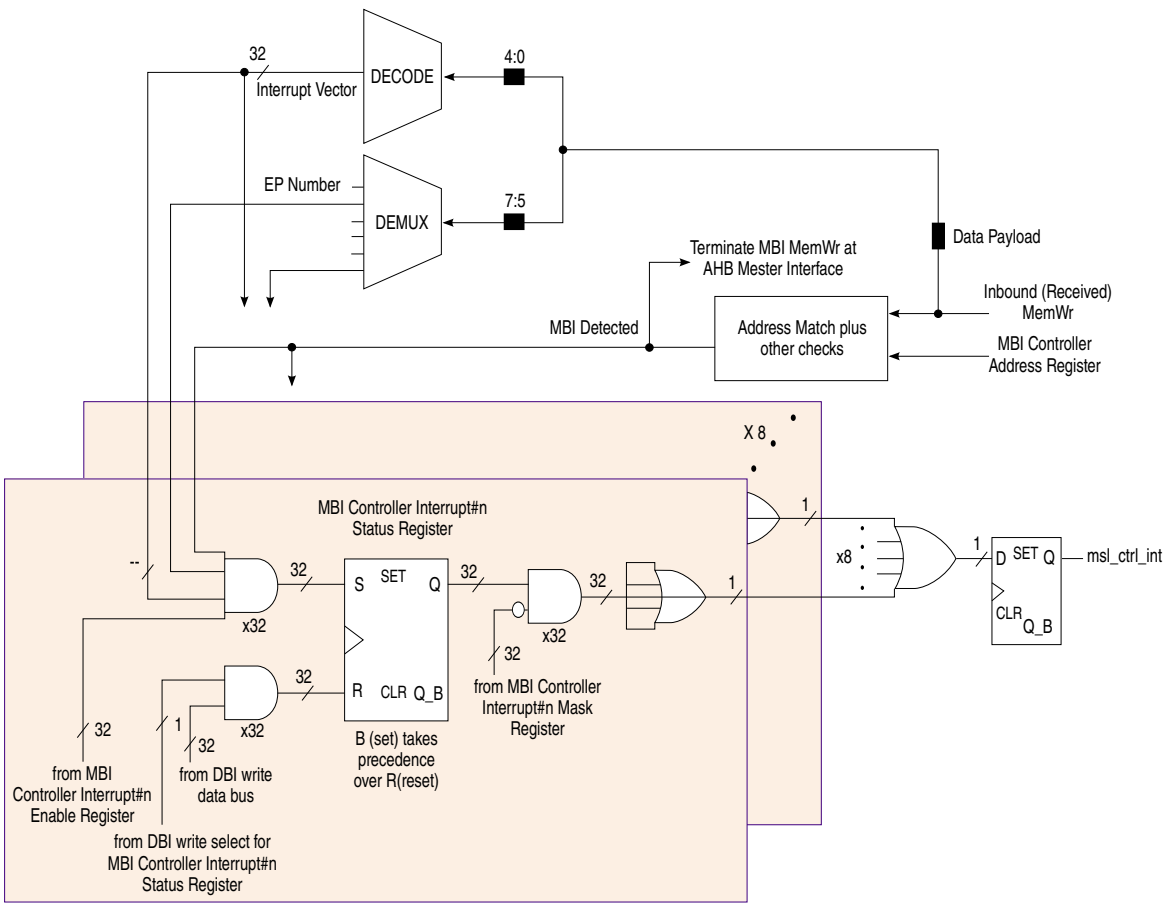

Figure 48-22. Architectural Representation of how the MSI Controller processes detected interrupts.

If the decoded Interrupt Vector is enabled and not masked then the corresponding bit is set in the Interrupt Status register (MSI Controller Interrupt#0 Status Register) and the top-level core output msi_ctrl_int is asserted. This signal remains asserted until the host CPU clears the status bit by writing a 1'b1 to the status bit. (Writing a 1'b0 has no effect). If any status bit remains set then msi_ctrl_int remains asserted. The Interrupt Status register provides a status bit for up to 32 Interrupt Vectors per Endpoint.

If the decoded Interrupt Vector is enabled but is masked then the corresponding bit is set in Interrupt Status register but the top-level core output msi_ctrl_int is not asserted.

If an MSI Interrupt Vector is received from an Endpoint but that Vector has not been enabled in the corresponding Interrupt Enable register (MSI Controller Interrupt#0 Enable Register) then no bit will get set in the Interrupt Status Register and msi_ctrl_int will not be asserted.

In addition, if no interrupts have been enabled in any of the eight Interrupt Enable Registers, then all MSI detection logic is disabled and valid MSI MWr request TLPs are not terminated in the bridge and are passed by the AHB/AXI master interface to the AHB/AXI bus.

The Interrupt Mask register (MSI Controller Interrupt#0 Mask Register) allows the Host to mask a given MSI Interrupt Vector. If a MSI Interrupt Vector is received for a masked Interrupt Vector, the corresponding bit in the Interrupt Status register will get set but msi_ctr_intl will not be asserted as the Interrupt Vector is masked. Note: This masking is local to the MSI Interrupt Controller and is not part of Per Vector Masking (PVM) in any of the downstream Endpoints.

The contents of the Interrupt Mask and Interrupt Status registers are used to drive the msi_ctrl_int output. If any status bit is set and the interrupt vector is not masked, then msi_ctrl_int is asserted HIGH.As long as any Interrupt Status bit is set and not masked, msi_ctrl_int will remain asserted.

ALTERNATIVE DATA REGISTER PROGRAMMING

The programming of the data register (MSI Data Registerwhich is part of the PCI Express MSI Capability Register structure) assumes each Endpoint enables 32 Vectors. If one or more Endpoints only support 16 or less Interrupt Vectors then it is possible to share a single set of Interrupt Enable, Interrupt Mask and Interrupt Status registers among those Endpoints.

For example, assume that Endpoint #1 enables 16 Interrupt Vectors and Endpoint #2 also enables 16 Interrupt Vectors. If the MSI Data register for Endpoint #1 is programmed to 0x20 and the MSI Data Register for Endpoint#2 is programmed to 0x30, then both Endpoint's Interrupt Status will be contained in Interrupt Status Register#1 with Endpoint#1's Vectors in the lower 16 bits and Endpoint#2's Vectors in the upper 16 bits. Manipulating the MSI Data Register format in this manner allows the Interrupt Controller to support more than 8 Endpoints using the 8 Interrupt Status registers provided.

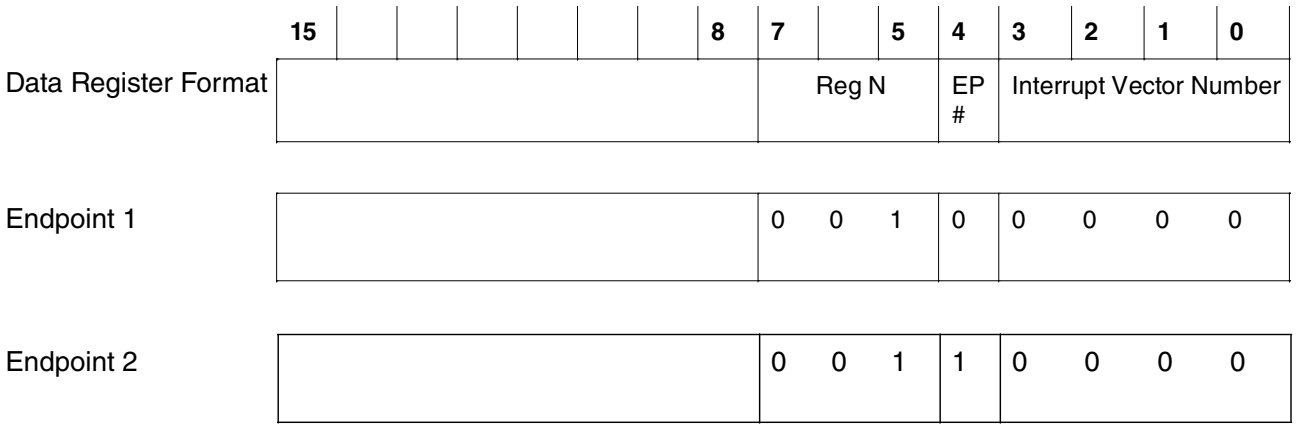

Figure 48-23. Alternative MSI Data Register Format

48.3.8 Flow Control

PCI Express implements a differentiated, credit-based Flow Control system to prevent overflows at the receiver.

In contrast to the simple XON/XOFF type flow control of the Ethernet protocol, the PCI Express Flow Control system requires that the consumer of data advertise the available buffer space for each type and priority of traffic. The Flow Control mechanism is divided into two phases: the initialization phase and the update phase. The core automatically performs both of these phases with minimal support required from the application.

The Flow Control for VC0 must be initialized following Link initialization, but prior to sending normal traffic. This initialization is performed by the Flow Control Initialization state machine. The initialization process involves exchanging information with the Link partner about the size of the receiver's buffers for each type of packet data: Posted, Non-Posted, and Completion. Header and payload buffers for each of these types are tracked and reported independently. Flow Control must be initialized for Virtual Channel 0 (VC0) before the Data Link Layer's link state moves into the DL_ACTIVE state, and normal traffic can begin flowing. Additional VCs (if any) are initialized following this, intermingled with the regular traffic already flowing on VC0. Initialization of other VCs begins when the VCs are enabled. The VC0 traffic has priority over non-VC0 flow control initialization.

The core provides a configurable solution to choose the number of credits to advertise per type and per VC. It can be configured to support multiple VCs as well as infinite credits. The core performs all required Flow Control protocol handshakes. The core currently provides a solution in which the application does not have to deal with Flow Control

updates and checks. By default, the RADM is responsible for returning Flow Control credits as data is read out of the RADM queuing structure. Additionally, the core provides optional signals to enable the application to handle Flow Control returns in an application-specific manner

The core does not return Flow Control credits for packets that have Data Link Layer errors.

48.3.9 Address Translation

This is a local address translation implementation and is not related to the PCI-SIG ATS specification support.

If address translation support is enabled for the core, it can use an address translation unit (ATU) to replace the TLP address and TLP header fields in the current TLP request header.

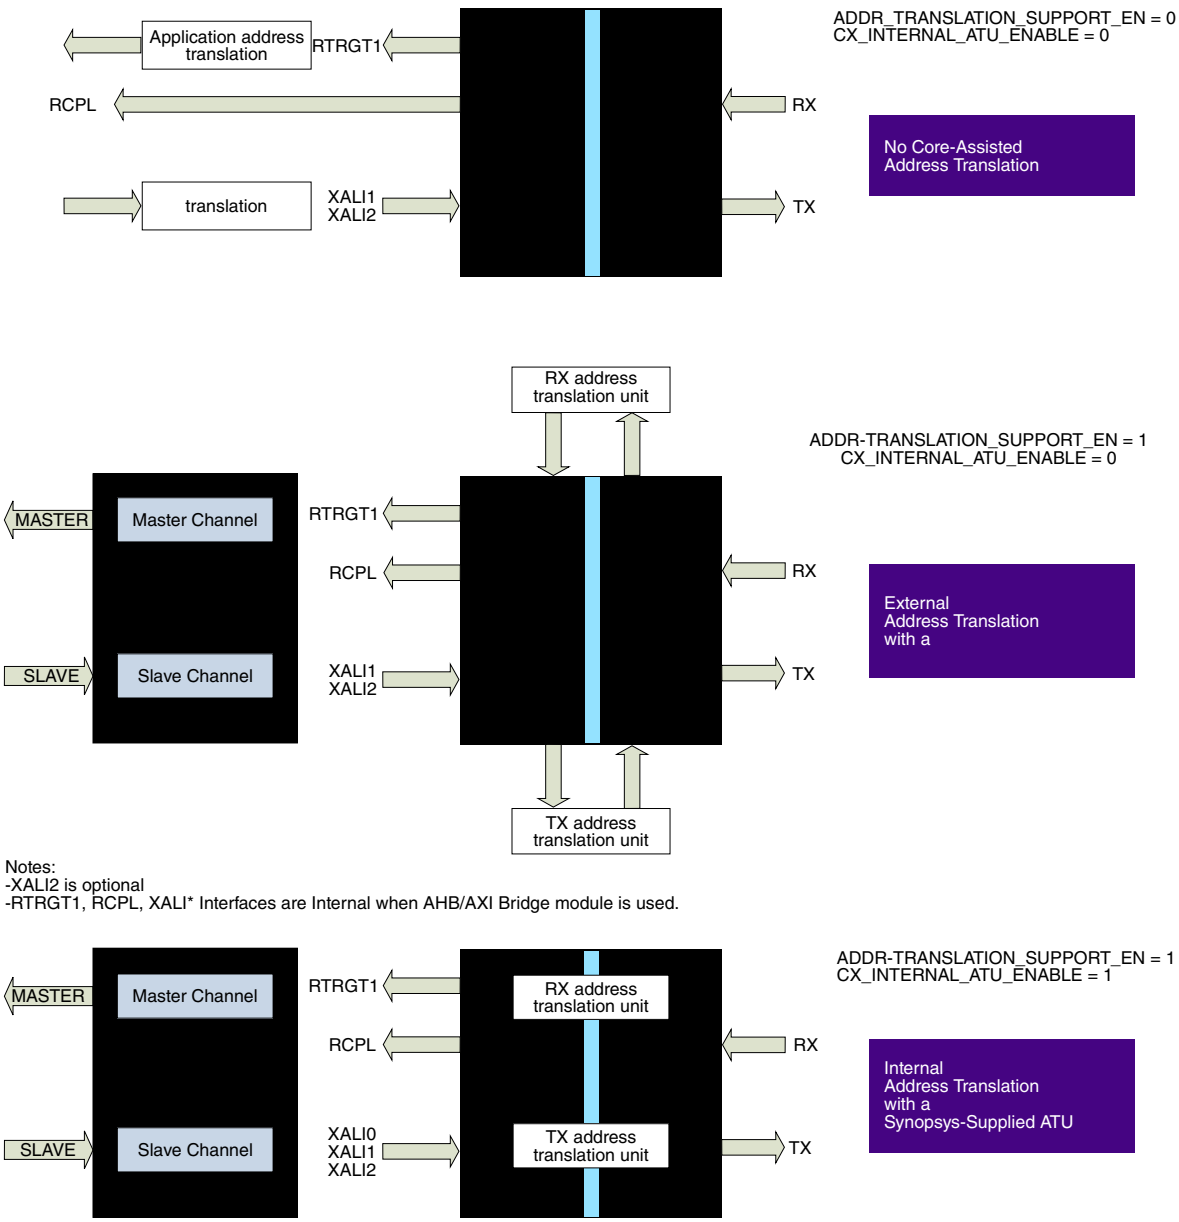

Figure 48-24. Address Translation options

Address translation is used for mapping different address ranges to different memory spaces supported by the application. A typical example will map the AMBA memory space to PCI memory space when the application has the PCIe-to-AMBA bridge in place. TYPE translation is also supported.

Without address translation, the application address is passed to/from the PCIe TLPs directly through AXI bridge interfaces.

The PCIe core supportsaddress translation.

1. Internal Address Translation (iATU) instantiates an internal ATU (iATU) inside the PCIe core. It can be configured (by software) to implement a customer-defined address translation scheme without the need for additional hardware from the customer. To enable this option:

Table 48-20. Configuration Parameters Relevant to Address Translation

Parameter Name	Parameter Label	Value Range	
CX_ATU_NUM_OUTBOUND_REGIONS	Number of Outbound Address Translation Regions	4,	
CX_ATU_NUM_INBOUND_REGIONS	Number of Inbound Address Translation Regions	4,1	
CX_ATU_MIN_REGION_SIZE	Minimum Size of Address Translation Region	64 kB	

NOTE

The easiest and recommended method of implementing address translation is to use the Internal Address Translation Unit (iATU).

48.3.9.1 Internal Address Translation (iATU)

An internal ATU (iATU) is instantiated inside the PCIe core.

It can be configured (by software) to implement a customer-defined address (and TYPE/ FORMAT) translation scheme without the need for additional external hardware.

48.3.9.1.1 Outbound (TX) Features

- Address Match Mode operation for MEM/IO/CFG/MSG TLPs. No address translation for CPL.
- Supports TYPE translation via TLP TYPE header field replacement for MEM[1] types to MSG/CFG types.
- This includes translation from Posted to Non-Posted (for example, MWr to CfgWr0).
- No TYPE translation from CPL TLPs.
- Programmable TLP header per region for the following fields for TLP field *replacement*.
- TYPE / TD / TC / AT / ATTR / MSG Code
- Function Number (Physical and Virtual).
- 4 Address Regions based on programmable registers for location and size.
- Programmable enable/disable per region.

- Automatic format (FMT) field translation between 3 DW and 4 DW for 64-bit addresses.
- Invert Address Matching Mode to translate accesses outside of a successful address match.
- ECAM Configuration Shift Mode to allow a 256 MB CFG1 space to be located anywhere in the 64-bit address space.
- Can be used to replace usage of misc sideband AXI slave bus signals.
- Supports regions from 64kB to 4 GB in size.
-

48.3.9.1.2 Inbound (RX) Features

- Address Match Mode operation for MEM/IO/CFG/MSG TLPs. No address translation for CPL. Selectable BAR Match Mode operation for IO/MEM TLPs.
- TLPs destined for RTRGT0 (internal CDM or ELBI) will not be translated.
- TLPs that are not error-free (ECRC, malformed and so on) will not be translated.
- Programmable TLP header per region for the following fields for *matching*.
- TYPE / TD / TC / AT / ATTR / MSG Code
- Function Number (Physical and Virtual).
- Up to 4 Address Regions based on programmable registers for location and size.
- Programmable enable/disable per region.
- Automatic format (FMT) field translation between 3 DW and 4 DW for 64-bit addresses.
- Invert Address Matching Mode to translate accesses outside of a successful address match.
- Configuration Shift Mode. Optimizes the memory footprint of CFG accesses destined for the AXI bridge interface in multi-function devices.
- Supports cores with and without the AHB/AXI Bridge module.
- Response Code defines the CPL completion status to return for accesses matching a region.
- Supports regions from64 kB to 4 GB in size.

48.3.9.1.3 Programming (iATU)

The iATU registers are in the PCIe cores' port logic register space (See PCIe CTRL Port Logic Memory Map/Register Definition). This may be accessed locally via the DBI interface or via PCIe Configuration accesses.

The following registers are used for programming the iATU.

Table 48-21. iATU Register Map

Byte Offset	Description

Table continues on the next page...

Table 48-21. iATU Register Map (continued)

+0x200	iATU Viewport Register
+0x204	iATU Region Control 1 Register
+0x208	iATU Region Control 2 Register
+0x20C	iATU Region Lower Base Address Register
+0x210	iATU Region Upper Base Address Register
+0x214	iATU Region Limit Address Register
+0x218	iATU Region Lower Target Address Register
+0x21C	iATU Region Upper Target Address Register

Full descriptions of each register are available at PCIe CTRL Port Logic Memory Map/ Register Definition.

48.3.9.2 Outbound iATU Operation

Information found here describes the processing of outbound requests by the iATU.

The topics for this section are:

- RID BDF Number Replacement
- iATU Outbound MSG Handling
- CFG Handling
- CFG Shift Feature
- FMT Translation
- Invert Feature
- No Address Match Result
- Writing to a MRdLk Region
- Programming Example

OVERVIEW (ADDRESS MATCH MODE)

The address field of each request MEM/IO TLP is checked to see if it falls into any of the enabled[1] address regions defined by the 'Start' and 'End' addresses. If an address match is found, then the TLP address field is modified as follows:

Address = Address - Base Address + Target Address

and the TYPE, TD, TC, AT and ATTR TLP header fields are replaced with the corresponding fields in iATU Control 1 Register.

If the application (AXI) address field matches more than one of the CX_ATU_NUM_OUTBOUND_REGIONS address regions, then the first (lowest of the numbers from 0 to CX_ATU_NUM_OUTBOUND_REGIONS-1) enabled region to be matched is used.

If there is no address match, then the address is untranslated. In the outbound direction (only), the TLP header information (for fields that are programmable) will come from the relevant fields on the AXI Slave Interface sideband busses (all fields will be 0).Since all misc_info are tied to 0, this is not recommended.

This operational mode (called Address Match Mode) is always used for outbound translation.

1. If the 'Region Enable' bit of the 'Region Control 2 Register' is '0', then that region is not used for address matching.

When the PCIe core is operating with 32-bit addresses, the operation is defined as in the following figure.

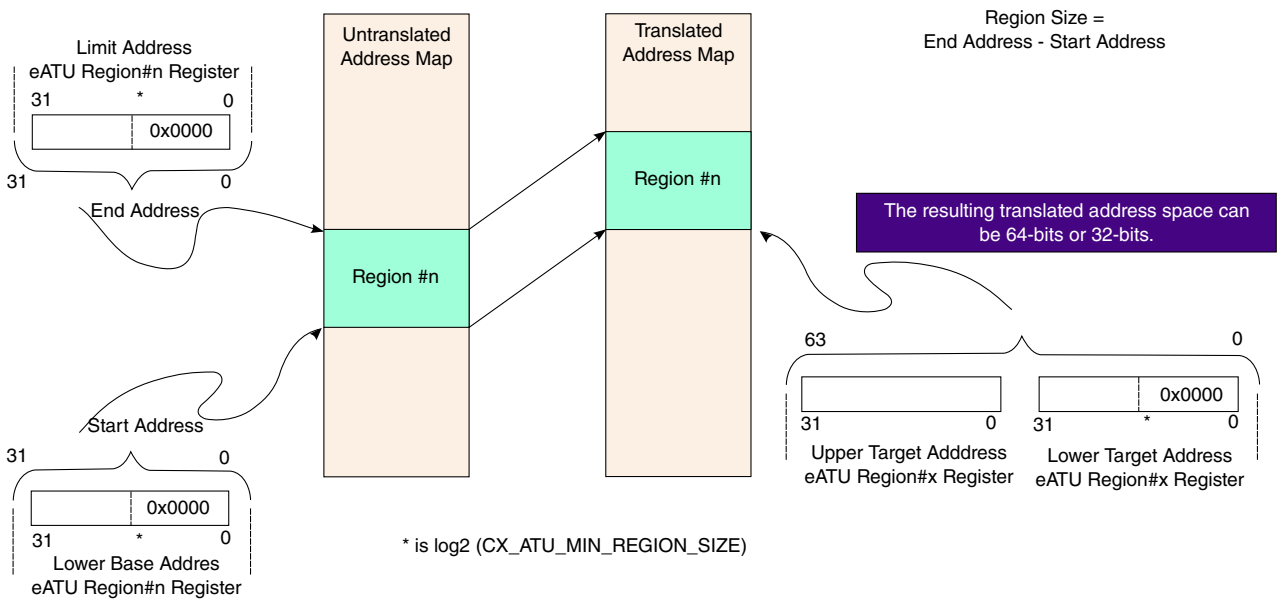

Figure 48-25. iATU Address Region Mapping: Outbound and Inbound (Address Match mode): 32-bit Address

The upper 32 bits of the Target Address Register will always form the upper 32 bits of the translated address because:

- The maximum region size is 4 GB.
- A region may not cross a 4 GB boundary.

The CX_ATU_MIN_REGION_SIZE (64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(CX_ATU_MIN_REGION_SIZE) bits are zero.

RID BDF NUMBER REPLACEMENT

When there is a successful address match on an outbound TLP, then the function number used in generating the 'Function' part of the Requester ID (RID[1]) field of the TLP is taken from the 3-bit 'Function Number' field of the iATU Control 1 Register. The value in this field must be 0x0 unless MultiFunction operation in the core is enabled (CX_NFUNC > 1).

iATU OUTBOUND MSG HANDLING

The iATU supports TYPE translation/conversion of MEM[4] TLP's to Msg/MsgD TLPs. This supports applications that are unable to generate Msg/MsgD type TLPs natively.

When there is a successful address match on an outbound MEM TLP, and the translated TLP TYPE field is 'Message' (that is, 'TYPE' field of the iATU Control 1 Register is 10xxx); then the Message Code field of the TLP is set to the value in the 'Message Code' field of the iATU Control 2 Register.

A MWr with an 'effective length of 0' (see [5]) is converted to Msg and all other MWr TLPs are converted to MsgD.

NOTE

For more information on generating Messages, see Message Generation.

For a proper understanding of Messages, you should be familiar with the PCI Express Base Specification.

MSG translation is possible with the iATU. For MSG transactions created directly by the application (as opposed to, by the iATU) you must ensure that the 3rd and 4th DWORD (In the PCI Express Base Specification) does not match any programmed iATU address region or else unintentional translation (TYPE) could occur.

RID uses the 8-bit.5-bit.3-bit PCI Bus.Device.Function (BDF) format.

The maximum size of this field is 8 bits, but the actual size depends on the number of Virtual functions (VFs) used as denoted by 2^NVF_WD Or IO.

For AXI, this takes the First and Last byte enables into account. For AXI this is through slv_wstrb. If you are just translating the address of MSG TLPs, then client0_tlp_byte_en is used to provide the Message Code.

CFG HANDLING

Outbound CFG transactions (formed by translation of IO/MEM TLPs from the application) can exist anywhere in address space -because the Routing ID or BDF, is created by the iATU from bits [31:16] of the untranslated address - and this BDF changes according on the PCIe bus topology.

In the normal untranslated transmission of CFG transactions, the PCIe core derives the CFG Bus.Device.Function (BDF) information from the address on the AXI Slave Interface address) as follows.

Table 48-22. Normal PCIe Core Outbound Derivation of BDF from XALI* or AHB/AXI Slave Interfaces

XAXI Slave Interface Bits	PCIe CFG Header Field
31:24	Bus Number
23:19	Device Number
18:16	Function Number
11:8	Extended Register Number
7:2	Register Number

The iATU supports translation (of address or type) of IO/MEM TLP's to CFG TLPs. This supports applications that are unable to generate CFG type TLPs natively.

The 16-bit Bus.Device.Function (BDF) is derived from bits [31:16] of the iATU Lower Target Address Register.

CFG translation is possible with the iATU. For CFG transactions created directly by the application (as opposed to, by the iATU) you must ensure that the Bus.Device.Function field does not match any programmed iATU address region or else unintentional translation (TYPE) could occur.

CFG SHIFT FEATURE

A expander feature (CFG Shift Feature) can be enabled by setting the 'CFG Shift' bit of the iATU Control 2 Register.

This shifts/maps the BDF - bits [27:12] of the Target Address up to bits [31:16] of the translated address. This allows all outgoing IO/MEM TLPs (that have been translated to CFG) to be mapped into any 256 MB region of the PCIe address space.

This scheme also supports the Enhanced Configuration Address Mapping (ECAM) mechanism from the *PCI Express, Revision 3.0 Base Specification.* ECAM supports the mapping (via MEM to CFG TYPE translation) from memory address space to PCI Express Configuration Space address. ECAM maps bits [27:12] of the untranslated MEM TLP to become the BDF of the resulting CFG TLP.

Table 48-23. ECAM Scheme from PCIe Specification using an 8-bit BDF Bus Number

Memory Address Bits	PCIe Configuration Space
27:20	Bus Number
19:15	Device Number
14:12	Function Number
11:8	Extended Register Number
7:2	Register Number

FMT TRANSLATION

The iATU automatically sets the TLP format (FMT) field for 3DW when it detects all zeroes in the upper 32- bits of the *translated* address. Otherwise, it sets it to 4DW when it detects a 64-bit address (that is, when there is a '1' in the upper 32-bits of the translated address). If the original address and the translated address are of different format, the iATU ensures that the TLP header size matches the translated address format.

INVERT FEATURE

Normally, an address match on an outbound TLP occurs, occurs when the untranslated address is in the region bounded by the Base Address and Limit Address.

When the Invert feature is activated, an address match occurs when the untranslated address is NOT in the region bounded by the Base Address and Limit Address.

This feature is activated by setting the 'Invert' field of the iATU Control 2 Register.

NO ADDRESS MATCH RESULT

When there is no address match, then the address is untranslated but

the TLP header information will come from the relevant fields on the AHB/AXI Slave Interface sideband busses (all fields will be 0).

WRITING TO A MRDLK REGION

When there is a successful address match for an outbound WRITE, and the TYPE header field - as replaced with the TPYE field in iATU Control 1 Register - is MRdLk, then the TYPE header field will be set to MEM (that is 00000b).

PROGRAMMING EXAMPLE

See #d9040e5a1310 for details on the programming registers.

NOTE

Define Outbound Region 1 as:

NOTE

IO region from 0x80000000_d000000 - 0x80000000_d000ffff (64k)

NOTE

mapped to 0x00010000 in PCIe IO space.

1. Setup the Viewport Register

Write 0x00000001 to Address { 0x700 + 0x200 } to set outbound region 1 as the current region

2. Setup the Region Base and Limit Address Registers

Write 0xd0000000 to Address {0x700 + 0x20C} to set the Lower Base Address. Write 0x80000000 to Address {0x700 + 0x210} to set the Upper Base Address. Write 0xd000ffff to Address {0x700 + 0x214} to set the Limit Address

3. Setup the Target Address Registers

Write 0x00010000 to Address {0x700 + 0x218} to set the Lower Target Address

Write 0x00000000 to Address {0x700 + 0x21C} to set the Upper Target Address

4. Configure the region via the Region Control 1 Register

Write 0x00000002 to Address {0x700 + 0x204} to define the type of the region to be IO.

5. Enable the region

Write 0x80000000 to Address {0x700 + 0x208} to enable the region.

48.3.9.2.1 Inbound iATU Operation

This section describe the processing of inbound requests by the iATU. The topics for this section are:

- Overview
- IO/MEM Match Modes
- CFG Handling
- Optional Matching Fields
- Response Code Feature

48.3.9.3 Overview (iATU)

The main difference between Inbound and Outbound iATU operation is that the TLP TYPE is never changed in the Inbound direction.

Instead, the TYPE field is used for more precise matching. Other fields may also be optionally used to further refine the matching process.

Another difference is that for MEM/IO TLPs, you can select between Address matching (as used in Outbound Operation) or BAR matching. Normally an End Point (EP) will use BAR match mode and a Root Complex (RC) will use Address mode as an RC normally has no BAR's implemented.

Lastly, for CFG0 TLPs, you can select between Routing ID matching or Accept mode.

If there is no match then the address is untranslated. In addition,

- TLPs destined for RTRGT0 (internal CDM or ELBI) will not be translated.
- TLPs that are not error-free (ECRC, malformed and so on) will not be translated.
- Address translation of all TLP types (MEM/IO/CFG/MSG) except CPL is supported in Address Match mode. In BAR Match mode only translation of IO/MEM is supported.

IO/MEM MATCH MODES

Inbound Address translation for IO/MEM TLPs will operate in one of two matching modes as determined by the 'Inbound Match Mode' field in the iATU Region Control 2 Register.

1. Address Match Mode

The operation is similar to Outbound iATU Operation.

The address field of each request TLP is checked to see if it falls into any of the enabled[1] address regions defined by the 'Start' and 'End' addresses. If an address match is found, then the TLP address field is modified as follows:

Address = Address - Base Address + Target Address

If the TLP address field matches more than one of the CX_ATU_NUM_INBOUND_REGIONS address regions, then the first (lowest of the numbers from 0 to CX_ATU_NUM_INBOUND_REGIONS-1) enabled region to be matched is used.

2. BAR Match Mode

Looking for an address match is a two-step process.

1. The address field of MEM/IO *(only)* request TLPs is checked by the standard internal *PCI Express BAR Matching Mechanism* to see if it falls into any address region defined by the enabled BAR Addresses and Masks.
2. If a matched BAR was found, then that matched BAR ID is compared by the iATU to the 'BAR Number' field in the iATU Region Control 2 Register for all enabled regions.

BAR Match Mode can only be used for MEM/IO transactions.

Address Match Mode should always be used to match MSG transactions as these will never generate a match against a BAR.

1. If the 'Region Enable' bit of the 'Region Control 2 Register' is '0', then that region is not used for address matching.

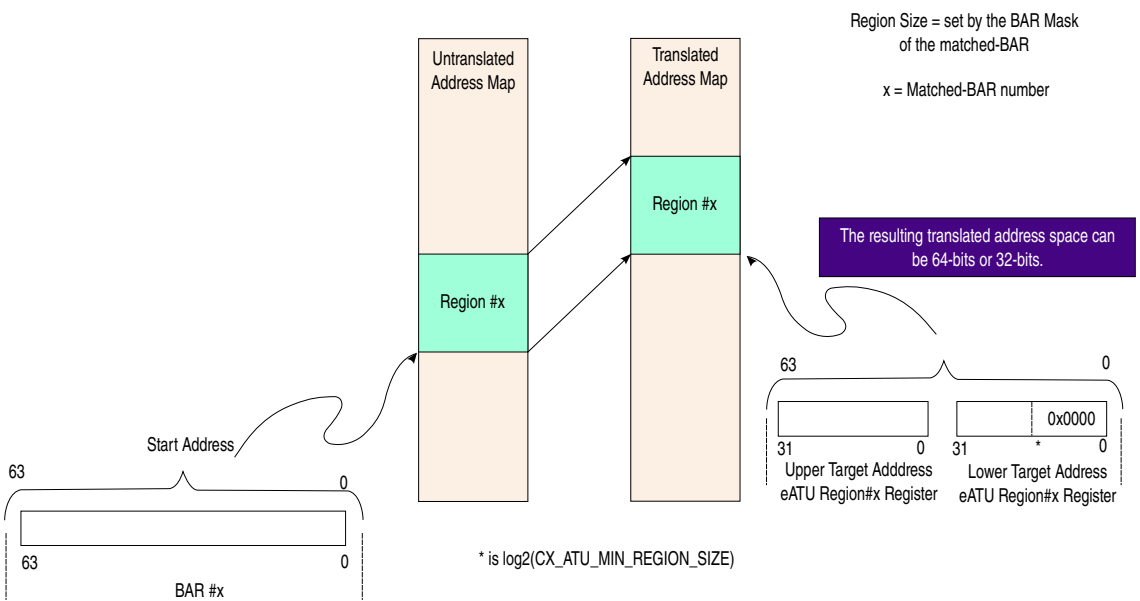

Figure 48-26. iATU Address Region Mapping: Inbound (BAR Match mode): 64-bit BAR

Normally an EP will use BAR match mode and an RC will use Address Match mode -as an RC normally has no BAR's implemented or at least must handle requests which do not match any of its BARs.

However, the user has the freedom to implement any mode in their device. For example, an EP device may use Address Match mode, but should be aware that if the address range does not match one of its BAR ranges in an EP, the device will reject the request with Unsupported Request (UR) completion status and no translation will occur.

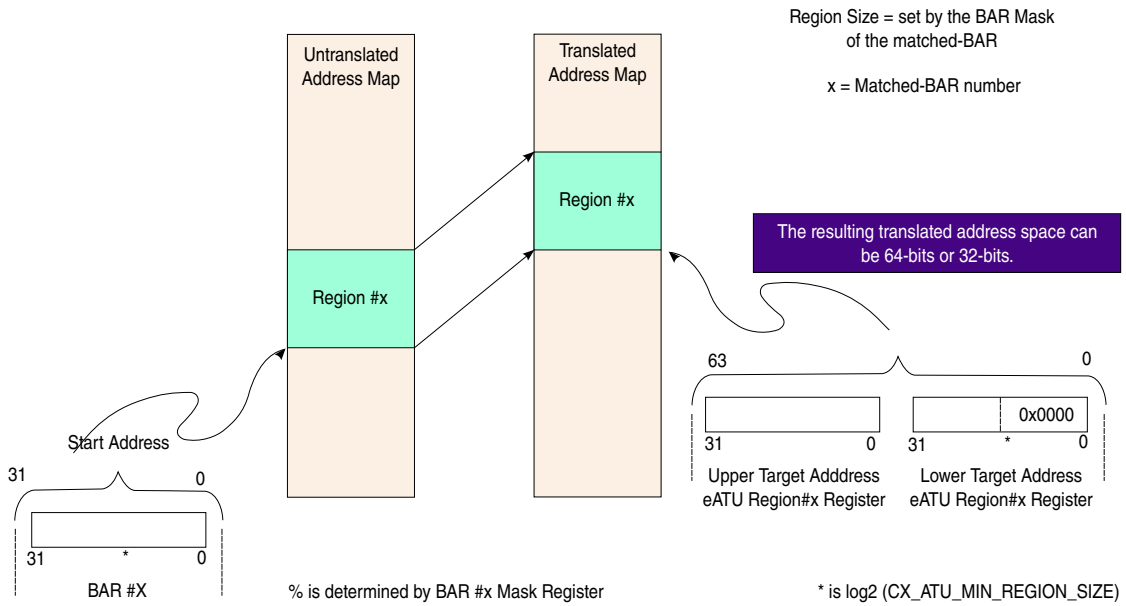

Figure 48-27. iATU Address Region Mapping: Inbound (BAR Match mode): 32-bit BAR

dress space

CFG HANDLING

CFG TLPs are normally routed to internal CDM. These will not be translated. Only CFG0 TLPs routed to AXI Bridge Master interface will be translated.

Inbound Address translation for CFG0 TLPs will operate in one of two matching modes as determined by the 'Inbound CFG0 Match Mode' field of the iATU Region Control 2 Register.

1. Routing ID Match Mode:

The operation is similar to outbound iATU operation. The Routing ID of the inbound CFG0 TLP must fall within the Base and Limit of the defined iATU region for matching to proceed. The iATU interprets the Routing ID (Bytes[1] 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM/IO transactions.

2. Accept Mode:

CFG0 TLPs should always be accepted and processed even if the bus number does not match the current Bus number of the device. This mode follows that behavior. The Routing ID of received CFG0 TLPs will be ignored when determining a match.

CFG1 TRANSACTIONS

For CfgRd1/CfgWr1 transactions the Base and Limit Address could enclose the entire 32-bit 4G memory space with Routing ID forming the upper 16 bits. The Target Address maps these CFG transactions to anywhere in application address space.

CFG SHIFT FEATURE

Inbound CFG transactions (routed for AXI Bridge Master) can exist anywhere in address space -because the Routing ID or BDF, is processed by the PCIe core RADM filter (see Receive Application-Dependent Module (RADM)) as bits [31:16] of an address - and this BDF changes according on the PCIe bus topology.

A compressor feature (CFG Shift Feature) can be enabled by setting the CFG Shift bit of the iATU Region Control 2 Register. Bits [15:12] of the 3rd DWORD[1] of CFG TLPs are reserved. The compressor feature uses this to reduce the memory requirement.

This shifts/maps the BDF - bits [31:16] of 3rd header DWORD which would be matched against the Base and Limit Addresses - of the incoming CfgRd0/CfgWr0 down to bits [27:12] of the translated address.

OPTIONAL MATCHING FIELDS

In Address or BAR Match mode, a successful address/BAR match can be optionally gated by successful matching of the following programmable TLP header fields (per region):

- TYPE / TD / TC / AT / ATTR
- MSG Code (MSG TLP's only)
- Function Number (MEM, IO or CFG TLPs only)
- Virtual Function Number (MEM or IO TLPs only)

For each of the above fields in the iATU Region Control 1 Register (ATU Region Control 2 Register for MSG) there is an associated 'Match Enable' bit in the iATU Region Control 2 Register. Address translation will only proceed if all enabled field-matches are successful.

If SR-IOV is enabled (CX_SRIOV_ENABLE=1), and the Virtual Function Match Enable field of the iATU Region Control 2 Register is set, then the 'Function' is no longer the 3-bit 'Function' but the combined 8-bit 'Device' 'Function' parts. When SR-IOV is enabled, the Alternate RID Interpretation (ARI) RID scheme is used. This uses a 8-bit.0-bit.8-bit BDF format. where the device number is assumed to be zero.

RESPONSE CODE FEATURE

When the 'Response Code' field of the inbound iATU Region Control 2 Register is set to a value other than 00b, it will determine the Completion Status of the CPL TLP sent in response to a successfully matched Non Posted TLP. This can be set to Unsupported Request (UR) or Completer Abort (CA). When the error response field is set to 00b, then the normal RADM (see Receive Application-Dependent Module (RADM)) filter response for this TLP will be used.

IATU INBOUND MSG HANDLING

Inbound Message (Msg/MsgD) transactions can use one of two matching modes:

Address Match Mode: The 3rd and 4th header DWORDs are treated as an address and matched against the iATU Region Base and Limit Address registers. Furthermore, for Vendor Defined messages, this allows specific vendor defined messages to be filtered into memory at the Target Address. The Upper Base Address should be set to Bus.Device.Function (BDF) and Vendor ID. The Lower Base Address can be used as a filter for specific messages.

Vendor ID Match Mode: This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the 3rd DWORD of the TLP header[1], but matches against the Vendor ID in bits [15:0] of the 3rd DWORD of the TLP header (bytes[1] 10 and 11). This allows Vendor defined messages to be filtered against specific Vendor IDs without needing to know the BDF number which may vary depending on the PCI topology.

Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID as follows:

- Region Upper Base[15:8] = byte 10
- Region Upper Base[7:0] = byte 11

The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the 4th DWORD of the TLP header.

NOTE

For more information on generating Messages, see Message Generation. For a proper understanding of Messages you should be familiar with Message Request Rules of the PCI Express Base Specification.

FUZZY TYPE MATCH MODE

When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that

- CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1.
- MRd and MRdLk TLPs are seen as identical
- The Routing field of MsgD TLPs is ignored

For example, CFG0 in the TYPE field in the iATU Control 1 Register will match against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP.

To enable this feature, then set the 'Fuzzy Type Match Mode' bit of the iATU Region Control 2 Register.

FMT TRANSLATION

The iATU automatically sets the TLP format (FMT) field for 3DW when it detects all zeroes in the upper 32- bits of the *translated* address. Otherwise, it sets it to 4DW when it detects a 64-bit address (that is, when there is a '1' in the upper 32-bits of the translated address). If the original address and the translated address are of different format, the iATU ensures that the TLP header size matches the translated address format.

INVERT FEATURE

Normally, an address match on an outbound TLP occurs, occurs when the untranslated address is in the region bounded by the Base Address and Limit Address.

When the Invert feature is activated, an address match occurs when the untranslated address is NOT in the region bounded by the Base Address and Limit Address.

This feature is activated by setting the 'Invert' field of the iATU Region Control 2 Register.

PROGRAMMING EXAMPLES

Define Inbound Region 2 as: MEM region matching BAR4 (BAR Match mode) mapping to 0x8000000020000000 in the application memory space

1. Setup the Viewport Register
   - Write 0x80000002 to Address { 0x700 + 0x200 } to set inbound region 2as the current region
2. Setup the Target Address Registers
   - Write 0x20000000 to Address {0x700 + 0x218} to set the Lower Target Address
   - Write 0x80000000 to Address {0x700 + 0x21C} to set the Upper Target Address
3. Configure the region via the Region Control 1 Register
   - Write 0x00000000 to Address {0x700 + 0x204} to define the type of the region to be MEM.
4. Enable the region for BAR Match Mode
   - Write 0xC0000400 to Address {0x700 + 0x208} to enable the region for BAR match mode for BAR#4.

Define Inbound Region 0 as: MEM region matching TLPs with addresses in the range 0x00010000 - 0x0005ffff mapped to 0x1000000020000000 - 0x100000002004ffff in the application memory space

1. Setup the Viewport Register
   - Write 0x80000000 to Address { 0x700 + 0x200 } to set inbound region 0 as the current region
2. Setup the Region Base and Limit Address Registers

- Write 0x00010000 to Address {0x700 + 0x20C} to set the Lower Base Address.
  Write 0x00000000 to Address {0x700 + 0x210} to set the Upper Base Address.
  Write 0x0005ffff to Address {0x700 + 0x214} to set the Limit Address

3. Setup the Target Address Registers
   - Write 0x20000000 to Address {0x700 + 0x218} to set the Lower Target Address
   - Write 0x10000000 to Address {0x700 + 0x21C} to set the Upper Target Address
4. Configure the region via the Region Control 1 Register
   - Write 0x00000000 to Address {0x700 + 0x204} to define the type of the region to be MEM.
5. Enable the region
   - Write 0x80000000 to Address {0x700 + 0x208} to enable the region in address match mode.
   - EP: Defined MEM or IO regions must be inside an enabled BAR range.
   - RC: Defined MEM or IO regions must either match a BAR or be outside of the base and limit ranges defined for the port in the Type 1 configuration header.

48.3.10 Gen2 5.0 GT/s Operation

The PCIe Express core supports all of the non-optional Gen2 5.0 GT/s features defined in the *PCI Express 3.0 Specification.*.

48.3.10.1 Overview (Gen2 5.0 GT/s)

The DWC PCIe cores support achives the PCI Express 2.0 rate, by DYNAMIC

FREQUENCY

1. When supporting Gen2 DYNAMIC FREQUENCY, the core operates at either 125 MHz at the Gen1 rate. When operating at the Gen2 rate, the core's clock frequency is changed to 250 MHz

Software configuration of Gen2 5.0 GT/s operation is available through the Gen2 Control Register.

48.3.10.2 Speed Changing

If bit 17 ìDirected Speed Changeì of the Gen2 Control Register is set to '1', then the LTSSM will initiate a speed change after the link is initialized. The default value of this register is the '1' .

A PIPE signal, mac_phy_rate, is used to negotiate the Link data rate. The core drives mac_phy_rate to indicate the negotiated Link data rate. For mac_phy_rate, a value of zero indicates 2.5 Gbps, and a value of one indicates 5.0 Gbps. The PCIe core changes the rate signal and waits for a pulse on the phy_mac_phystatus signal to confirm that the PHY has accepted the requested rate.

The PCIe core uses core_clk to sample the phy_mac_phystatus signal during speed changes. The PHY generates phy_mac_phystatus based on pipe_clk. Therefore, the following restrictions are placed on DWC_pcie external logic when the PHY is Gen2 Dynamic Frequency and the PCIe core is Gen2 Dynamic Width (i.e. when core_clk is not equivalent to pipe_clk).

1. ensure that core_clk is toggling when the PHY returns phy_mac_phystatus for a speed change

OR

2. the external logic must hold phy_mac_phystaus (for the speed change) until core_clk toggles again

For other configurations, the core_clk is equivalent to the pipe_clk, and this restriction is not needed.

48.3.11 Power Management

An architectural overview of the Power Management Controller is given in "Power Management Controller (PMC)".

There are two types of power management operations:

- Software controlled PCI power management operations
- Active state power management operation (ASPM) for PCIe device only

The following figure shows the capable link state and its control conditions.

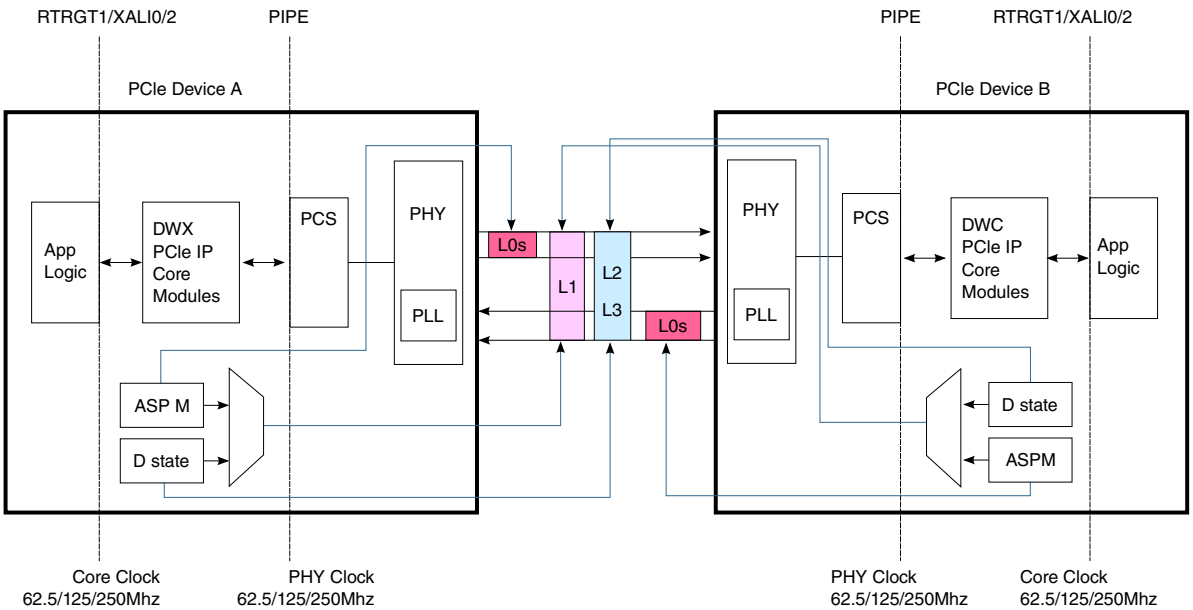

Figure 48-28. Power Management - Capable Link State and Control Conditions

The L0s link state is controlled by the ASPM L0s enter condition met state. The L1 link state is controlled either by the ASPM L1 enter condition met state, or by the D-state (D1, D2, or D3) of the PCIe device. The D- state of the PCIe device is programmable by software. The L2/L3 ready state is controlled by D-state and power turn-off event.

The power saving of links in lower power states is greater as the link state numbers get larger. The following figure shows the links states of PCIe devices and the relationships of power down states between link partners.

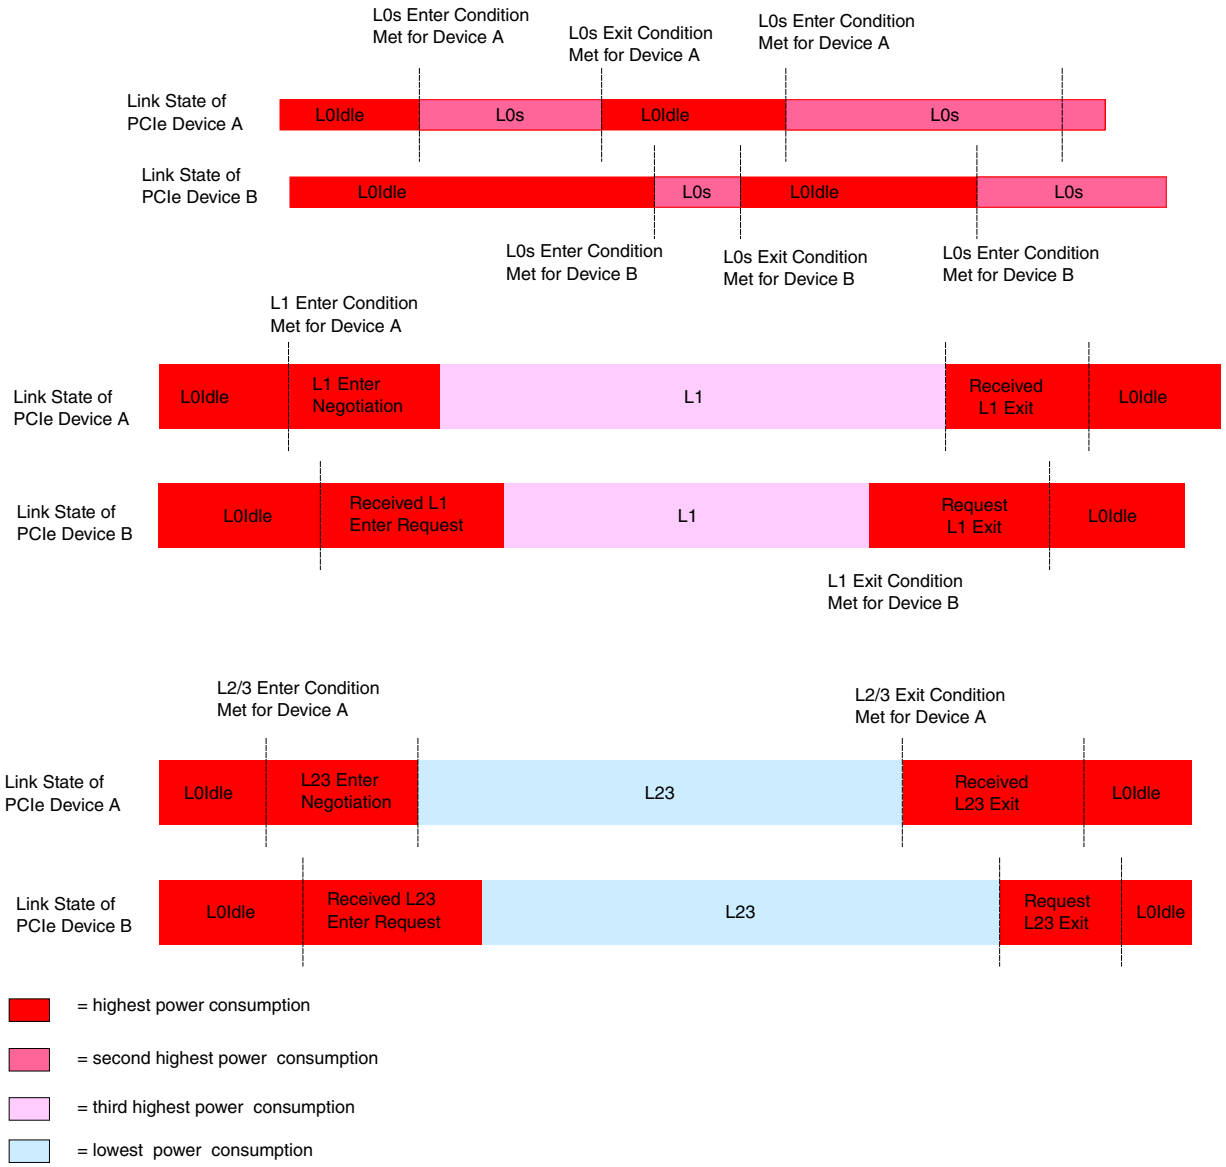

Figure 48-29. Relationships of Power Down States between Link Partners

48.3.11.1 L0s Power Down

L0s is a low power state enabled by Active State Power Management (ASPM). ASPM enabled devices can only control L0s entrance of the transmitter. The receiver L0s is controlled by the remote devices.

L0S ENTER CONDITIONS (ALL CONDITIONS MET)

- ASPM L0s is enabled.
- L0s enter conditions defined by *PCI Express Specification* for a duration of time and there is no higher stage of power down requested.
- The timeout value is controlled by the DEFAULT_L0S_ENTR_LATENCY parameter.

L0S EXIT CONDITIONS (ANY CONDITION MET)

- Any DLLP or TLP pending to be sent.
- L1 enter condition met.
- PCIe link partner request to enter into link recovery.

48.3.11.2 L1 Power Down

L1 is a power down state enabled either by ASPM or by the software controlled D1, D2 or D3 state (which is programmed by the system power management unit). L1 state is a bi-directional link power down state. Both link partners must negotiate to go to L1 state.

L1 ENTER CONDITIONS DUE TO ASPM (ALL CONDITIONS MET)

There are three scenarios that result in the L1 state:

- Scenario 1: L1 Idle Timeout From L0s

ASPM L1 and L0s are enabled.

Link state is in L0s for both transmitter and receiver of the link, and bit 30 of the Ack Frequency and L0-L1 ASPM Control Register is set to 0 (default setting) OR Link state is in L0s of transmitter and bit 30 of the Ack Frequency and L0-L1 ASPM Control Register is set to 1.

L1 enter conditions defined by PCIe spec for a duration of time and there is no higher stage of power down requested.

The timeout value is controlled by the DEFAULT_L1_ENTR_LATENCY parameter.

- Scenario 2: L1 Idle Timeout from L0

ASPM L1 is enabled and L0s is not enabled.

Link state is in L0.

L1 enter conditions defined by PCIe spec for duration of time, and there is no higher stage of power down requested.

The timeout value is controlled by the DEFAULT_L1_ENTR_LATENCY parameter.

- Scenario 3: Application Controlled

ASPM L1 is enabled.

Application request to enter L1 by asserting signal app_req_entr_l1

L1 enter conditions defined by PCIe spec is met.

NOTE

The app_req_entr_l1 is a pulse. The core latches the command and makes sure that L1 has been entered.

L1 ENTER CONDITIONS DUE TO D1/D2/D3 STATES (ALL CONDITIONS MET)

- All functions that are programmed to D1, D2 or D3 states.
- Always enter L1 when L2/L3 PM turn-off negotiation has not yet been done.

L1 EXIT CONDITIONS (ANY CONDITION MET)

- Software requests a higher stage of power down.
- Any DLLP or TLP pending to be sent.
- Application requesting exit of L1 by asserting signal app_req_exit_l1.
- Link partner requesting exit of L1.

Once L1 has exited, another L1 entry will not be initiated for 10us if the enter L1 condition is due to ASPM. If the enter L1 condition is due to lower power D-state, the core will enter L1 again after a wait time of cfg_cpl_sent_count cycles defined in PL register. This wait time to ensures the exit conditions have been served.

3.14.3 L2/L3 Power Down

The core has control over the L2 or L3 ready link state. After the L2/L3 ready is entered, the downstream device will begin preparation for the power and clock removal. After main power has been removed, the link will transition to L2 if Vaux is provided, or it will transition to L3 if no Vaux is provided. L2/L3 ready is a bi-directional link power down state.

L2/L3 ENTER CONDITIONS (ALL CONDITIONS MET)

- PME_Turn_Off/Pme_To_Ack handshake has been completed at any of D0,D1,D2,D3 states.
- Application is ready to be turned off by asserting signal app_ready_entr_l23.

L2/L3 EXIT CONDITIONS (ANY CONDITION MET)

- Device is programmed with capability to support PME and application requests wakeup by asserting the apps_pm_xmt_pme signal or by triggering a native hot-plug event when D-state is in D1, D2 or D3.
- Link partner requesting exit of L2/L3.

The core supports beacon signaling by asserting signal pm_phy_beacongen or wake when a wake-up event is initiated by a PCIe device.

48.3.12 Completion Timeout Ranges

Timeout ranges are supported as defined in the *PCI Express 3.0 Specification*.

The Device Capabilities 2 Register (Offset 24h) shows support for all ranges. The Device Control 2 Register (Offset 28h) will have a reset value equal to the default value in the spec: "0000b Default range: 50 us to 50 ms". If the default value is used then the timeout will be in "Range B: 0101b: 16ms to 55ms." This range was chosen for the default because the *PCI Express 3.0 Specification* states "It is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms." The following table illustrates the specification values versus the PCI Express core values for the ranges.

NOTE

As per the PCIe 2.1 spec, "This mechanism is intended to be activated only when there is no reasonable expectation that the Completion will be returned, and should never occur under normal operating conditions."

Table 48-24. PCIe Core Completion Timeout Ranges versus PCI Express Specification

Range	Encoding	Spec Minimum	Spec Maximum	PCIe Core Minimum	PCIe Core Maximum
Default	0000b	50µs	50ms	28ms	44ms
A	0001b	50µs	100µs	65µs	99µs
A	0010b	1ms	10ms	4.1ms	6.2ms
B	0101b	16ms	55ms	28ms	44ms
B	0110b	65ms	210ms	86ms	131ms
C	1001b	260ms	900ms	260ms	390ms
C	1010b	1s	3.5s	1.8s	2.8s
D	1101b	4s	13s	5.4s	8.2s
D	1110b	17s	64s	38s	58s

48.4 AXI Bridge Module

48.4.1 Product Overview

48.4.1.1 Overview

The PCIe Core provides an AXI Bridging capability for directly adding a PCI Express link to an AXI system fabric. This significantly reduces the time to design PCI Express into an AXI-based SOC.

The AXI Bridge Module acts as a bridge between the standard AXI interfaces and the PCIe Core native interfaces. The bridge interconnects the AXI interfaces within an AMBA-embedded system with a remote PCIe link, as either a root complex port or as an endpoint port. The bridge supports up to two AXI interfaces, one for an AXI master, and one AXI bus shared for AXI Slave and DBI bus access to the native PCIe core.

The AXI master interface enables a remote PCIe device to read and write to an AXI slave connected to the AXI bridge. The AXI slave interface enables an AXI master to read and write through the AXI bridge to a remote PCIe device. The slave DBI (see DBI Access) enables an AXI master to read and write to registers inside the native PCIe core, It is shared with the AXI slave interface.

Throughout this chapter, the terms inbound and outbound are defined with respect to the AXI fabric. That is, inbound transactions are defined as the transactions presented by the native PCIe core's AXI master interface. Outbound transactions are defined as the transactions generated by an AXI master that targets a remote PCIe device.

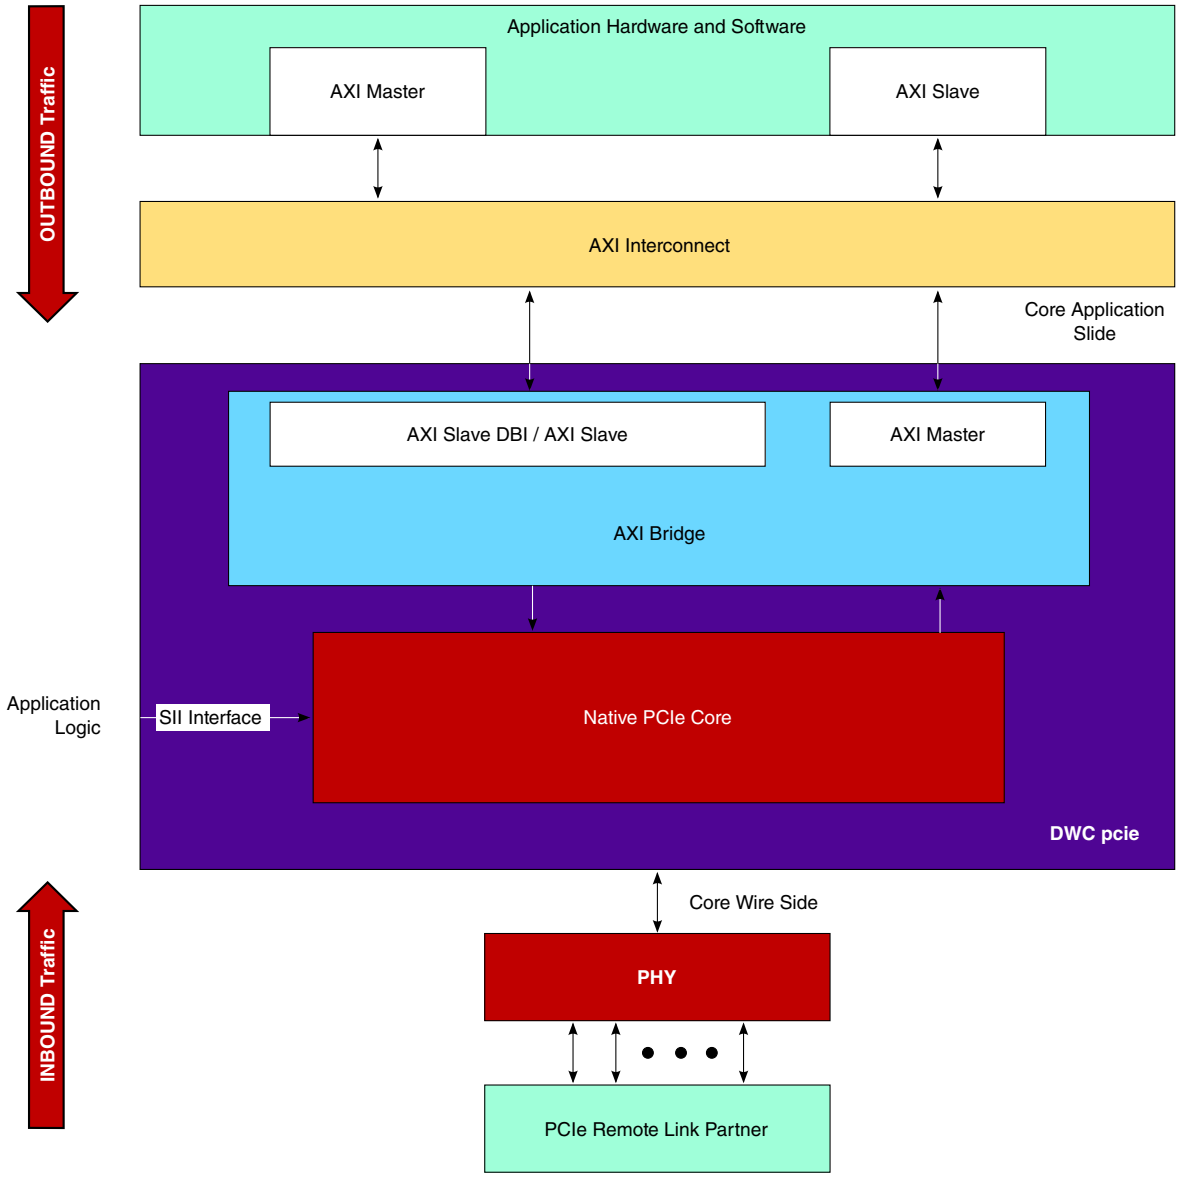

Figure 48-30. System-Level View of the DWC PCIe AXI Core

48.4.1.2 Interfaces

The figure below shows the DWC PCIe AXI core top-level interfaces.

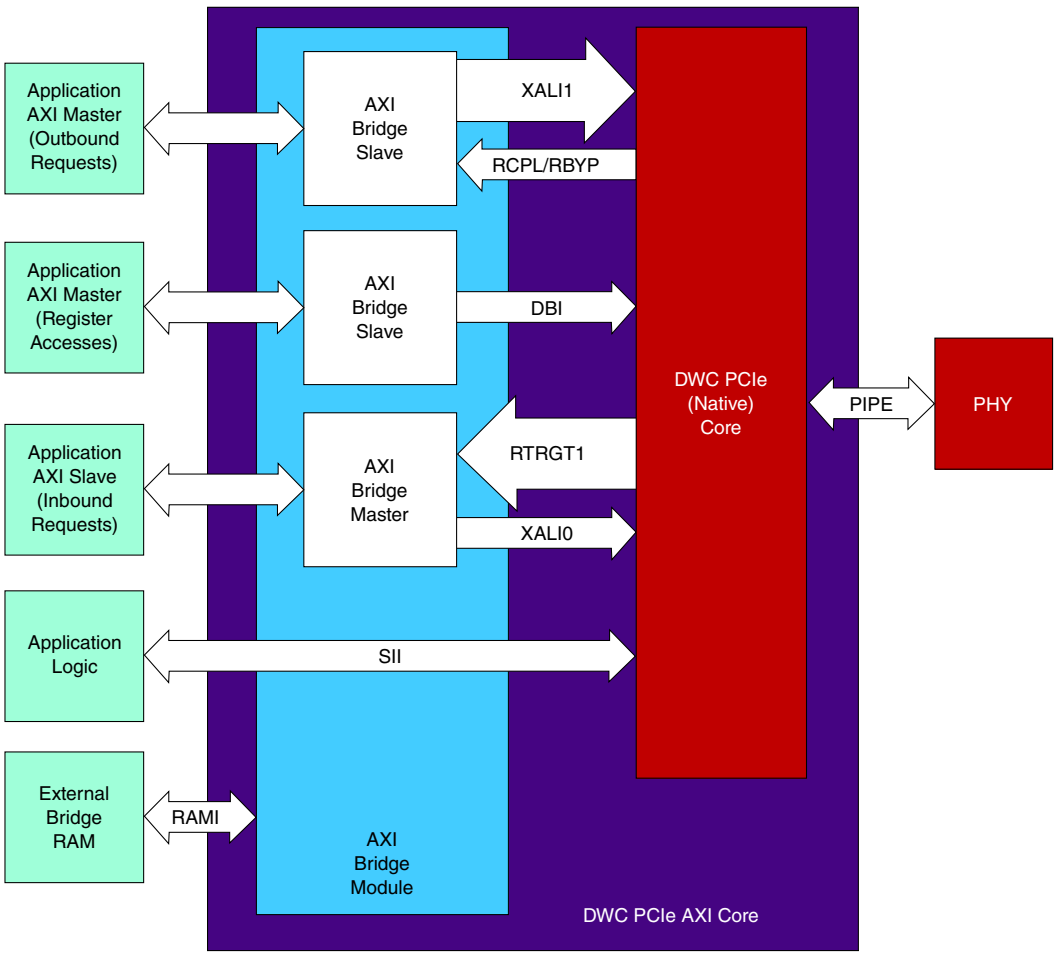

Figure 48-31. DWC PCIe AXI Core Top-Level Interfaces

For definitions of acronyms used for block and interface names, see Terms and Abbreviations.

48.4.1.3 Features List

The AXI Bridge Module supports the following features.

- AXI Master and Slave interfaces for inbound and outbound PCI Express requests.
- Multi-function support (up to 8 functions) [EP mode only].
- All types of PCI Express transactions supported through the AXI Bridge.
- A shared AXI Slave interface to access native core's CDM registers
- Programmable buffer sizes for AXI master and slave requests.

- Independent programmable user-defined clock rates for the PCI Express core, AXI master bus, AXI slave bus,.
- Programmable maximum number of outstanding inbound and outbound read requests for AXI.
- All burst-sizes supported for both AXI master and slave interfaces.
- Programmable and extended AXI burst lengths to support up to 4K read/write burst lengths over AXI master and slave interfaces.
- Little-endian operation.
- Independent maximum read request and transfer sizes between AXI and PCI Express (transfers can be split into multiple transfers).
- Response to AXI slave request combined gathering from split PCI Express completions that are received in-order.
- Response to AXI master request combined gathering from multiple AXI responses.
- PCIe legacy interrupt or MSI support.
- User-defined error mapping between PCI Express errors (UR, CA, CRS, poisoned, and ECRC error) and AXI slave response errors (SLVERR and DECERR).
- User-defined error mapping between PCI Express errors (UR, CA, CRS, poisoned, and ECRC error) and AXI master response error (DECERR_W and DECERR_R).
- Programmable byte parity check for the address and data buses throughout the bridge.
- Non-contiguous byte enables supported for inbound read/write and outbound write TLPs.
- Programmable MSI Interrupt controller to detect and terminate inbound MSI TLP's in the bridge for RC and DM (RC mode) products.

48.4.1.4 Limitations

The table below identifies the limitations encountered when using the AXI bridge with the DWC PCIe native core.

Table 48-25. AXI Bridge Limitations

AXI Bridge Limitation	Note
PCIe completions of a decomposed outbound AXI read request must be returned in-order.	Decomposition of outbound reads will not occur if your application master always generates read requests of size less than Max_Read_Request_Size. If decomposition occurs, and the remote device (or switch) is reordering completions, then corruption will occur at the Slave Response Composer in the AXI bridge. The Slave Response Composer only performs only in-order reassembly. In this case, you can set the AMBA Multiple Outbound Decomposed NP Sub-Requests Control Register to '0' to avoid corruption, at the expense of some performance.

Table continues on the next page...

Table 48-25. AXI Bridge Limitations (continued)

	See Outbound Ordering Limitation #1 for more details.
Posted and non-posted AXI writes targeting the bridge slave should use different AXI tags in order to allow the relevant B-channel responses to be received in order	See Outbound Ordering Limitation #2 for more details.
The AXI bridge only supports the CPL queue in ìStore and Forwardî mode, when a ìSegmented Queueî architecture is used. Otherwise, the CPL queue operates in Bypass mode, as it does for the ìSingleî and ìMultipleî queue architectures.	Set completions (CPL) to Bypass mode if you have not configured the core to use a segmented buffer queue architecture. See Queue to Port Mapping.
Vendor Messages must not be decomposed.	See AHB/AXI Message Address and Size Limitations for more details.
Big-endian operation is not supported	-
PCIe Advanced Error Reporting (AER) is not supported in the AXI bridge.	AER is only supported with respect to the native PCIe core. Errors detected by the bridge are not reported as part of AER.

48.4.2 Bridge Architecture

48.4.2.1 Bridge Architecture Overview

This module contains AXI master and slave protocol handlers, internal slave and master control for generic request and response interfaces, a packet composer, and a packet decomposer for response formation.

The slave and master protocol handlers support the AXI protocol conversion between an AXI transfer and a generic transfer within the bridge. The slave and master generic interface (GIF) supports the conversion of an AXI transfer to a PCIe transaction. The packet decomposer and composer support the segmentation and reassembly of a PCIe transaction.

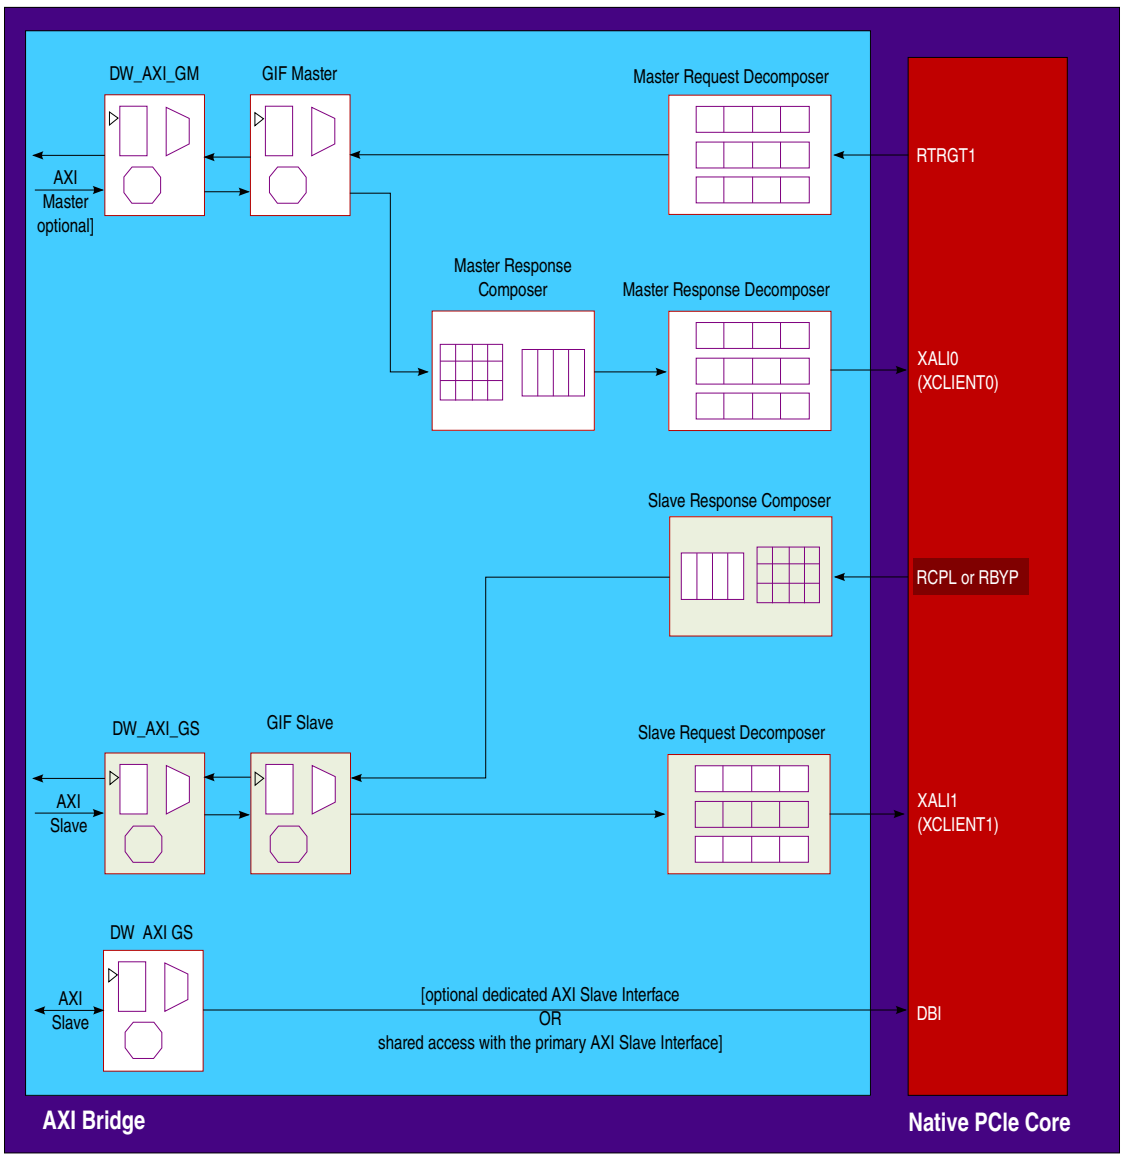

Figure 48-32. AXI Bridge Module, Block Diagram

The bridge module provides flexible buffering (Bridge Buffering) and tag management (Outbound Bridge Tag Management) to facilitate seamless bridging between the PCI Express native core and your application modules.

It has an optional master interface and a second optional slave (DBI) for accessing local registers in the native core CDM. Note also that DBI access is without the second slave (DBI). In this mode (shared DBI) the single slave is used to access both the DBI and the PCIe link.

48.4.2.1.1 Inbound Processing Module Chain

The following table lists the bridge modules involved in processing inbound requests.

Table 48-26. Bridge Modules Involved in Processing an Inbound (PCIe -> AXI) Requests

Module	Processing Step	Function
Master Request Decomposer	Request	Performs packet segmentation to satisfy the AXI fabric's "Max Burst Size" and "4KB Address Boundary" rules. These rules are discussed in Bridge Buffering.
Generic InterFace (GIF) Master	Request	The internal bridge circuitry is based on a generic protocol (GIF) and is not explicitly aware of whether it is interfacing to AXI or AHB.
Master Interface (DWC_axi_gm)	Request	This is the AXI protocol handler.
Master Response Composer	Response (Completion)	Performs packet reassembly caused by the bridge-initiated packet segmentation on the inbound request in the Master Request Decomposer.
Master Response Decomposer	Response (Completion)	Performs packet segmentation to satisfy PCI Express "Max Payload Size" and "Max Read Request Size" rules. These rules are discussed in Bridge Buffering.

48.4.2.1.2 Outbound Processing Module Chain

The following table lists the bridge modules involved in processing outbound requests.

Table 48-27. Bridge Modules Involved in Processing an Outbound (AXI -> PCIe) Requests

Module	Processing Step	Function
Slave Interface (DWC_axi_gs)	Request	This is the AXI protocol handler
Generic InterFace (GIF) Slave	Request	The internal bridge circuitry is based on a generic protocol (GIF) and is not explicitly aware of whether it is interfacing to AXI or AHB.
Slave Request Decomposer	Request	Performs packet segmentation to satisfy PCI Express ìMax Payload Sizeî and ìMax Read Request Sizeî rules. These rules are discussed in Bridge Buffering.
Slave Response Composer	Response (Completion)	Performs packet reassembly caused by the following sources of segmentation: •Bridge initiated packet segmentation on the outbound request in the Slave Request Decomposer. •Packet segmentation caused by the remote completer.

The application master request (at the AXI Slave Interface) will not - AXI protocol demands it - request more than 128 bytes and will not issue a request that involves crossing a 4K page boundary. Therefore the AXI response (completion) - composed from one or more completions that arrive in off the PCIe wire -is AXI compliant and does not need to be processed in a decomposer to enforce AXI page boundary and maximum packet size rules. Therefore there is no Slave Response Decomposer in the bridge module. In contrast, there is a Master Response Decomposer.

NOTE

CC_SLV_MTU

Also known as CC_SLV_RD_REQ_SIZE

This value is used to set memory sizes in the bridge (Slave Request Decomposer Data FIFO and Slave Response Composer).

Calculated as CC_SLV_BURST_LEN * (SLAVE_BUS_DATA_WIDTH / 8) = 16 * 64 / 8 = 128

CC_SLV_BURST_LEN is the maximum burst in beats that the application will ever issue to the bridge slave interface.

48.4.2.2 Decomposition

The bridge manages the different transfer sizes between PCIe and AXI.

The maximum payload is configured independently between the AXI and PCIe systems. Each system's transfer size will sometimes need to be converted causing a split of a request and composition of a response.

Automatic segmentation and reassembly of outbound (application to PCIe wire) packets is performed to satisfy PCI Express *Max_Read_Request_Size* and *Max_Payload_Size* rules. When a decomposition rule is triggered, the outbound TLP is broken up into two or more smaller TLPs. If the TLP type is Non Posted then additional PCIe TAGs are used from the TAG pool. Additional entries in the outbound header buffer are also used.

In a similar manner, automatic segmentation and reassembly of inbound packets is performed. The same AXI ID is used for all decomposed Non-Posted (but not for Posted; see Inbound Bridge Tag Management) packets.

The host software can program the PCIe device to support certain maximum write transfer sizes and maximum read request sizes. The native PCIe core's configuration module contains the device's *Max_Payload_Size* and *Max_Read_Request* size information, which are defined by the application software. The AXI bridge supports mismatches that occur when the AXI maximum transfer length is different than the *Max_Payload_Size* and *Max_Read_Request* size. For example, an inbound read transfer has an associated response buffer that is dependent on the remote PCIe device's *Max_Read_Request* size. An inbound write transfer has a master write buffer that is dependent on the remote PCIe device's *Max_Payload_Size*.

More detailed information on decomposition rules and effects is available at the end of the AXI bridge section at AXI Decomposition Rules.

48.4.2.3 Bridge Buffering

The bridge has additional buffering in addition to buffering already present in the native core.

The following table identifies all of the RAMs that are used in the AXI bridge for buffering purposes.

Table 48-28. Lists of Buffering Related RAMS

RAM Name	Alternative Name
Slave Request Decomposer Header and Data Queues : buffering of Outbound AXI Request	XADMX1 Decomposer Header and Data RAMs
Slave Response Composer : buffering of Inbound Responses to Outbound AXI Request	RADMX Composition RAM
Slave Response Asynchronous Clock Crossing FIFO : synchronization of Inbound Responses to Outbound AXI Request	RADMX Asynchronous RAM
Master Request Decomposer Header and Data Queues : buffering of Inbound PCIe Request	RADMX Decomposer Header and Data RAMs
Master Response Composer : buffering of Outbound Responses to Inbound PCIe Request	GM Composition RAM
Master Response Decomposer Header and Data Queues : buffering of Outbound Responses to Inbound PCIe Request	XADMX0 Decomposer Header and Data RAMs

More detailed information on buffering is available at the end of the AXI bridge section at Outbound Bridge Tag Management .

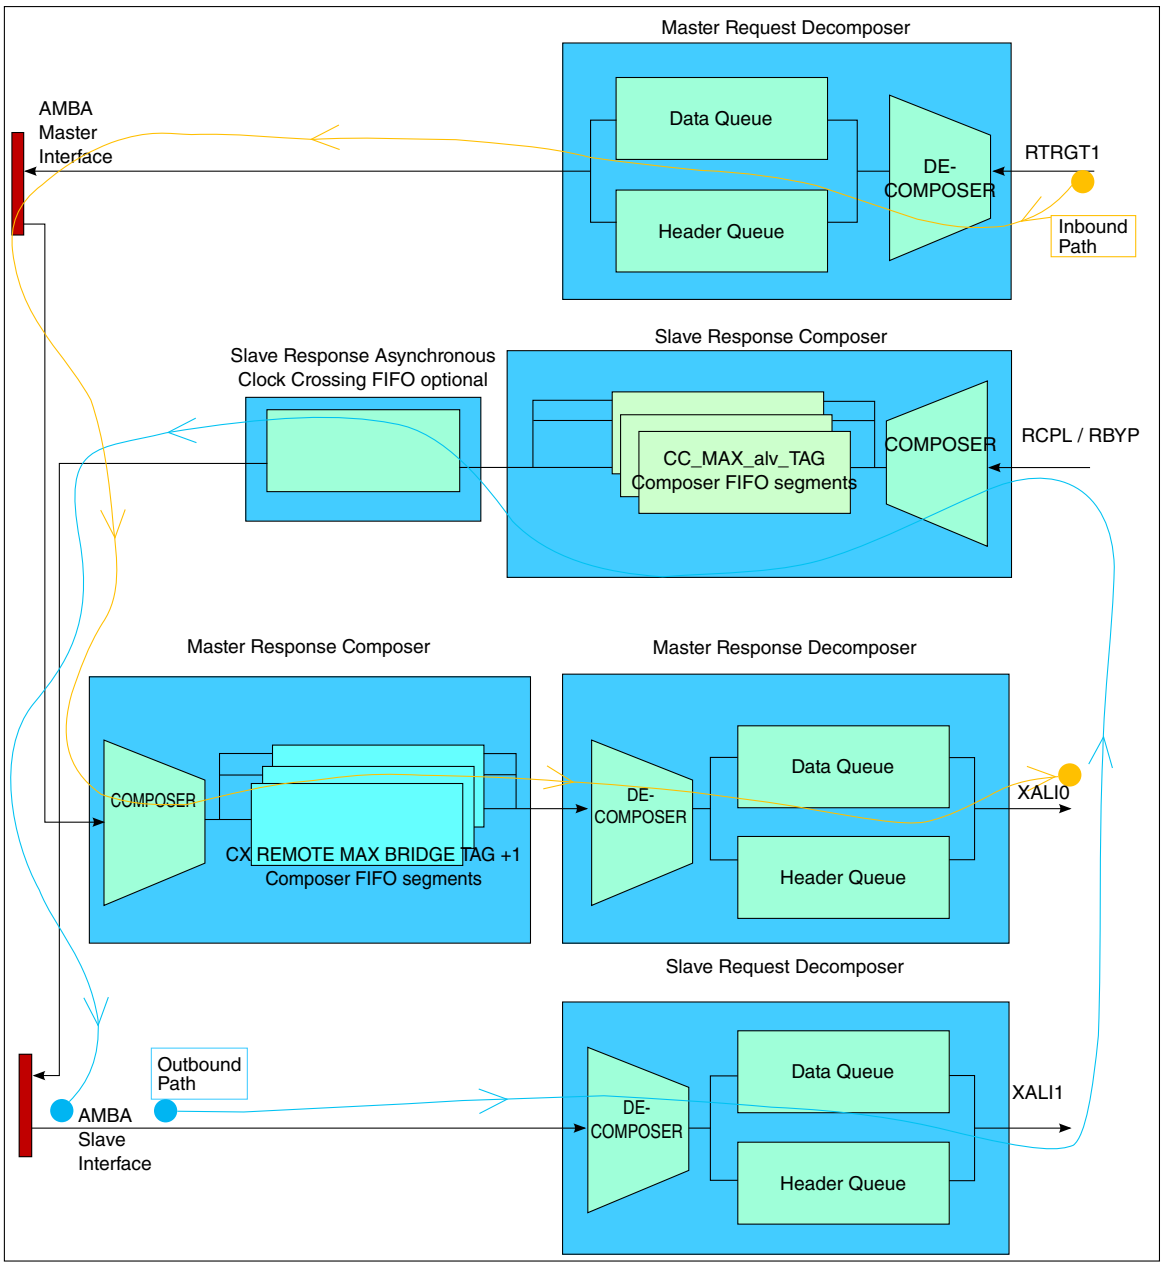

Figure 48-33. Overview of Bridge Buffering

48.4.2.4 Outbound Bridge Tag Management

The bridge transfers IDs/TAGs between PCIe and AXI.

Transactions on PCIe and AXI bus have separate IDs/TAGs and as the bridge transfers the data, it maps and keeps track of the IDs/TAGs on each side.

The diagram found here gives an overview of the outbound tag management system for Non Posted requests.

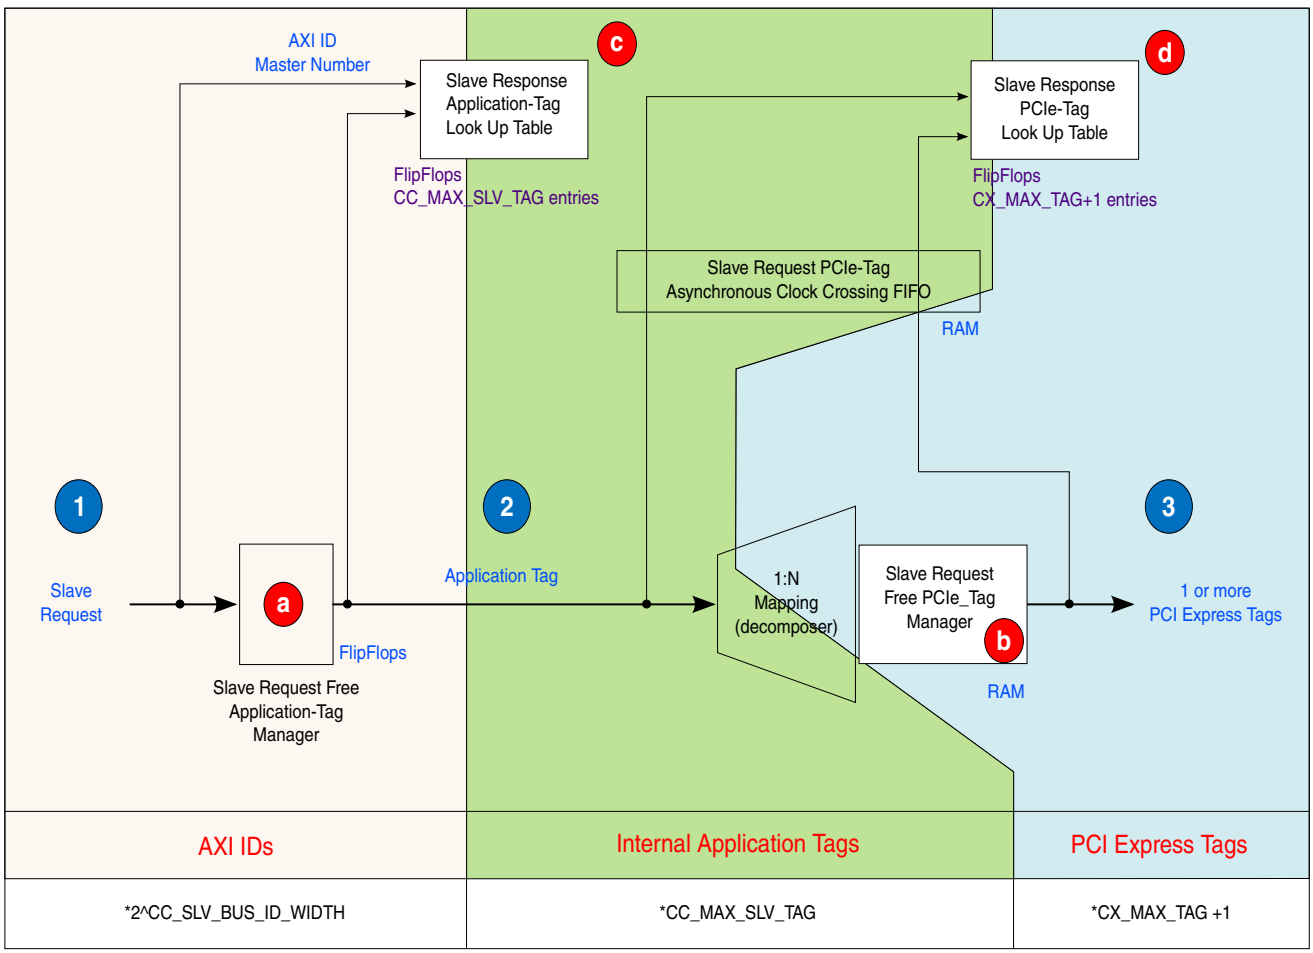

Figure 48-34. Outbound Tag Management Architecture (Non Posted requests only) - request path is shown but completion path is omitted.

When an AXI outbound Non Posted request at the slave interface is converted to a PCIe request TLP, it is necessary to:

- Select a PCIe tag from the 'free' pool of currently available PCIe tags. This is performed using a Tag Manager (see Module 'b' in figure above). When the pool is exhausted, no more PCIe request TLPs can be transmitted until the pool is replenished by tags from inbound PCIe completion TLPs. See steps 2 and 3 in figure above.
- Store the mapping from AXI request to PCIe TAG, so that when the corresponding PCIe completion TLP arrives back in the future, it can be correctly associated with

the originating request. This is achieved using a Tag Look Up Table (LUT) - see Module 'd' in figure above.

The process of mapping AXI requests IDs to PCIe tags is a two-step process - Application Tag mapping and PCIe Tag mapping (as described above).

Application Tag mapping -which is internal to the bridge -is an intermediate step which has to occur first. See steps 1 and 2 in figure above.

In the AXI protocol, it is possible to have several AXI requests with the same AXI ID. Therefore it is necessary for the bridge to differentiate between individual AXI requests to enable it to track them and their completions throughout the system.

This is necessary to aid in reassembling or recomposing (but not necessarily re-ordering, see Outbound Ordering Limitation #1 for more details) the multiple inbound completions that are returning for an original single AXI outbound request.

Multiple completions can occur due to decomposition (see Decomposition) of the original outbound request or due to the remote link partner choosing to complete a request using multiple completions.

Application tag mapping occurs via the following process:

- The bridge maps the AXI ID to an internal application tag (see Module 'a' in figure above). This application tag identifies the reserved space in the Slave Response Composer for the expected returning completions.
- The bridge store the mapping from the AXI ID to the internal application tag, so that when the corresponding PCIe completion TLP arrives back in the future, it can be correctly associated with the originating request. This is achieved using a Tag Look Up Table (LUT) - see Module 'c' in figure above.
- If decomposition occurs, each PCIe TLP is assigned a unique PCIe tag from the pool of CX_MAX_TAG (31) tags (see Module 'b' in figure above). Each of these PCIe tags is associated with the same internal application tag and this information is stored is a LUT (see Module 'c' in figure above).

If at any time, all PCIe TAGs or internal application tags are consumed, then the AXI Bridge Slave interface will not accept any new transactions and will apply back-pressure to the AXI fabric.

48.4.2.5 Inbound Bridge Tag Management

The bridge transfers IDs/TAGs between PCIe and AXI.

Transactions on PCIe and AXI bus have separate IDs/TAGs and as the bridge transfers the data, it maps and keeps track of the IDs/TAGs on each side. When an inbound PCIe request TLP is converted to an AXI request at the master interface, it is necessary to:

- Select an AXI ID from the 'free' pool of currently available AXI IDs.
  - For Non Posted requests, this is done using an ID Manager - see Module 'b' in the figure below.
  - Posted (P) requests always use ID '0'.
- When the pool is exhausted, no more requests can be launched onto the AXI fabric until the pool is replenished by IDs. An ID is released to the pool when the completion has arrived back from the application AXI master. In the case where the inbound PCIe TLP request was decomposed, then the ID is released when all the individual completions have arrived back into the master response composer.
- Store the mapping from PCIe TAG to AXI request ID to, so that when the corresponding AXI response arrives back in the future, it can be correctly associated with the originating request. This is achieved using an ID Look Up Table (LUT) - see Module 'a' in the figure below.

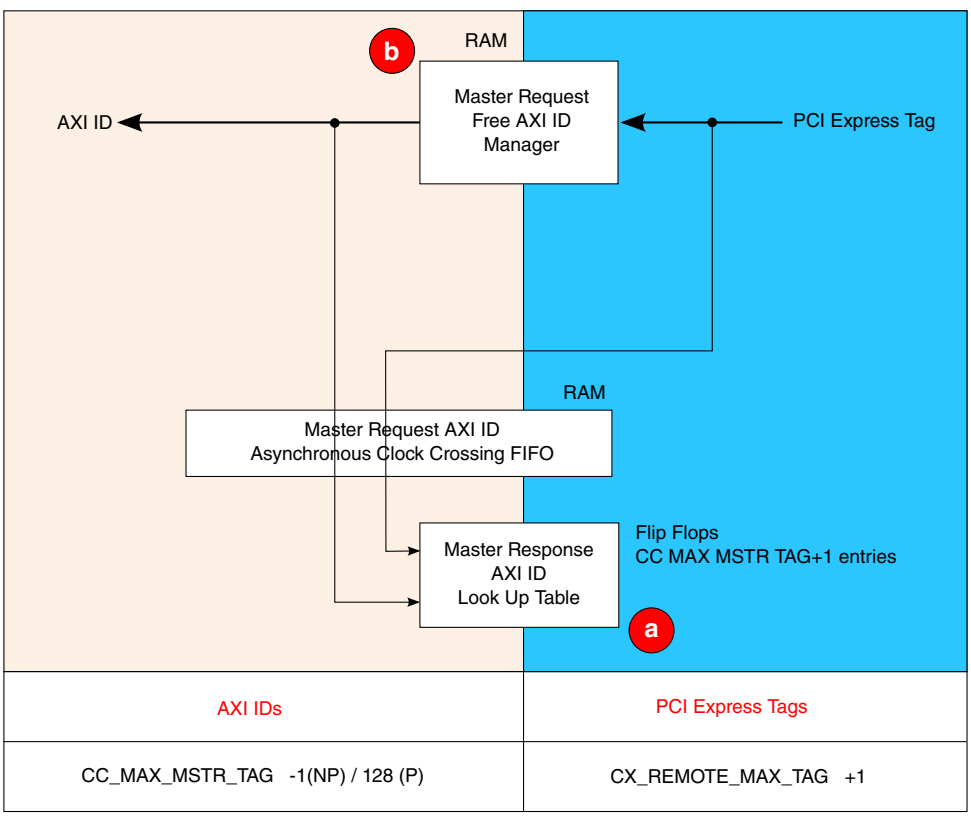

Figure 48-35. Inbound Tag Management Architecture - request path is shown but completion path is omitted.

Decomposition (Decomposition) does not affect AXI ID usage. If decomposition is occurring, then the same ID is used for each AXI request that is generated by decomposition. Each response is identified by the AXI bridge using its response ID.

Since the PCIe Posted transfer expects no response (completion) for a Posted request, the AXI bridge drops the write responses.

The AXI bridge master interface issues all Posted requests with an ID of '0'. The AXI bridge master interface issues Non Posted requests with an ID from the range 1 to CC_MAX_MSTR_TAG -1 (4-1=3).

It is possible to have CC_MAX_MSTR_TAG-1 (4-1=3). outstanding Non Posted requests and 128 Posted requests at the same time since Posted requests are always writes and use a different AXI ID signal (mstr_awid). The following memory devices are connected with inbound tag management in the bridge.

48.4.2.6 Inbound Order Enforcement for AXI Bridge

The DWC PCIe AXI bridge has the inbound buffers shown in the figure found here.

- a single FIFO queue structure (Master Request Decomposer Data and Header Queues) for inbound read/write requests
- a segmented buffer queue structure (Slave Response Composer) for inbound completions in response to outbound read requests.

There is no reordering after an inbound request has left the native core's receive queue. The request FIFO is blocking and will not allow read or write requests pass each other. This default design architecture is designed to serve inbound traffic as a FIFO (first-come, first -served) i.e. in-order service.

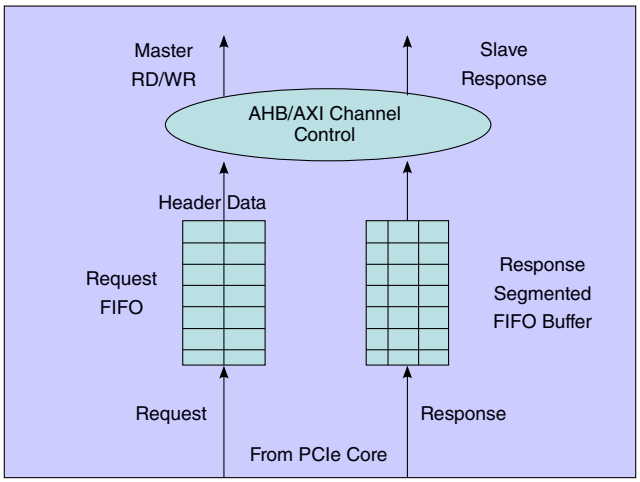

Figure 48-36. DWC PCIe AXI Bridge Inbound Traffic Queue Architectures

The native core (before the bridge) has flexible buffering (see Queue to Port Mapping and PCIe order rule enforcement is performed within the native core. See PCIe Core Inbound Order Enforcement.

48.4.2.6.1 Ordering Enforcement Hardware Lock Feature

Once a completion has been taken out of the receive queues of the DWC PCIe core, it can pass a posted request.

To enforce the PCIe Ordering rule ìcompletions should not pass posted if relaxed ordering is not setî for applications that require it, the DWC PCIe AXI bridge employs a hardware lock mechanism feature.

This feature will prevent completions from passing posted requests by requiring that posted transactions all complete through the bridge to an AXI interface before a completion can be taken out of the receive queue. This ensures that previous posted transactions are never passed by a completion. This feature is turned on when the DWC PCIe core is configured to have a receive queue in the segmented buffer mode and completion is in store-forward mode.

The feature employs packet halt signals generated by the bridge and used by the core when deciding how to unload the segmented buffer queue of the core. There is an individual halt signal for posted, non posted and completion transactions. Completion transactions are halted when there are any posted transactions in the bridge FIFO.

The limitation of the above feature is that it gives the posted transactions priority such that it can always pass through the bridge when it is available, while the completions are blocked.

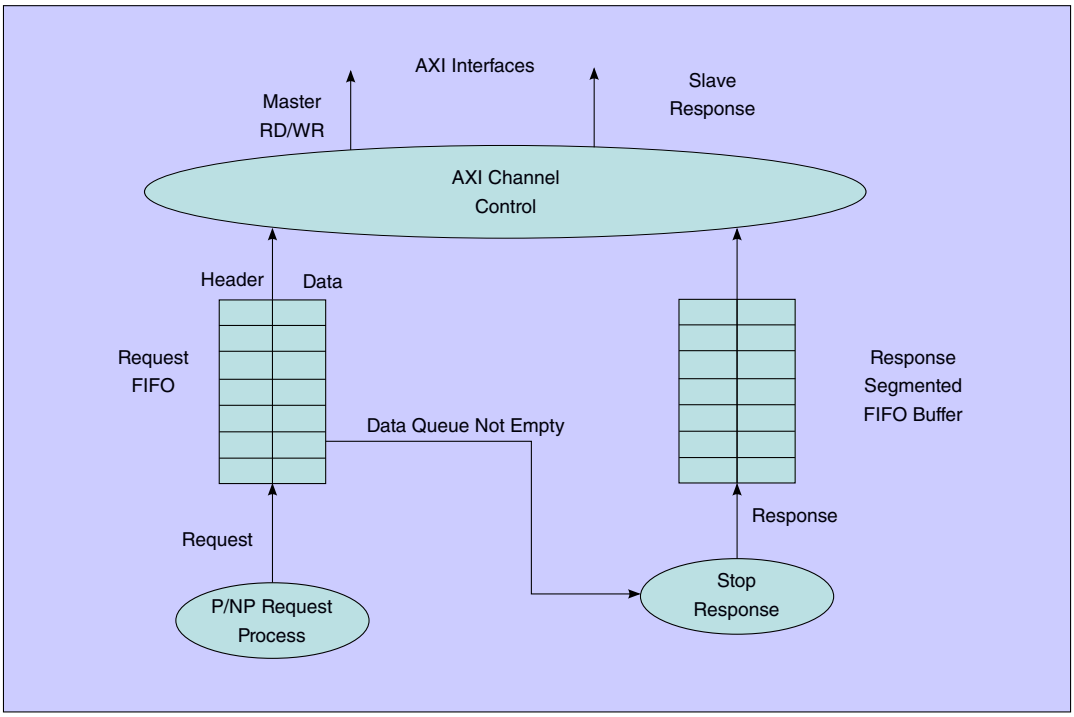

Figure 48-37. DWC PCIe AXI Bridge Inbound Traffic Order Enforcement

48.4.2.6.2 Re-Ordering Effects of AXI Fabric

The ordering rules, in typical AXI bridge configurations, apply only to the PCIe native core inbound queue and not after the inbound or outbound traffic has reached the AXI bridge. This means, for example, if a posted request followed by a completion reaches the AXI bridge, then it is possible that the completion will reach the AXI slave response channel before the posted reaches the AXI master request channel. This depends on the readiness of AXI master request channel (if wait states are asserted by the AXI bus).

The AXI bridge has independent AXI channels for outbound and inbound transfers. Therefore, a read response can be presented on the read outbound AXI channel while a write request is being presented onto the write inbound AXI channel. Since the response of an outbound read and inbound write request can be presented onto the application logic of AXI simultaneously, then the PCIe traffic order rules do not get completely enforced by most AXI bridge applications.

The AXI bridge master will generate a unique ID for each Non-Posted request (If decomposition is occurring, then the same ID is used for each AXI Non Posted request. For more details see Decomposition and Inbound Bridge Tag Management). Each response is identified by the AXI bridge using its response ID.

The AXI bridge master interface issues a Posted request (write) with a unique ID that is independent from master reads. Since the PCIe Posted transfer expects no response, the AXI bridge drops the write responses. If decomposition is occurring, then a unique ID is used for each AXI write request. For more details see Inbound Bridge Tag Management.

48.4.2.6.2.1 Inbound Ordering Limitation

Sometimes a Non-Posted transaction can pass a Posted transaction on the AXI fabric and this is a violation of the ordering rules. The AXI master interface does not wait for a write response - when it issues write transactions on the AW channel - before issuing a read transaction issued on the AR channel. As a result, a read transaction issued on the AR channel (after a write transaction on the AW channel) could complete first. This could happen if the AXI fabric delays completion of a write request (for example, due to latency in a write buffer) and a read request from the same address follows the write.

NOTE

For information on AXI ID generation see Inbound Bridge Tag Management.

48.4.2.6.3 Additional Information (ordering)

- Order enforcement through the native core is discussed in App Note: Order Enforcement Using the PCIe Core.
- Outbound Order Enforcement for AXI Bridge

The DWC PCIe AXI bridge has the following outbound buffers (see the figure below):

- a single FIFO queue structure (Slave Request Decomposer Data and Header Queues) for outbound read/write requests
- a segmented buffer queue structure (Master Response Composer) for outbound completions in response to inbound read requests.

These two queues are independently structured. Therefore, there is no order maintained (between completions and requests) once outbound requests or outbound responses have entered the bridge.

The FIFO is blocking and will not allow read or write requests pass each other. This default design architecture is designed to serve outbound traffic as a FIFO (first-come, first -served) i.e. in-order service. Outbound requests are served onto the PCIe wire in the order that they are received from an AXI master.

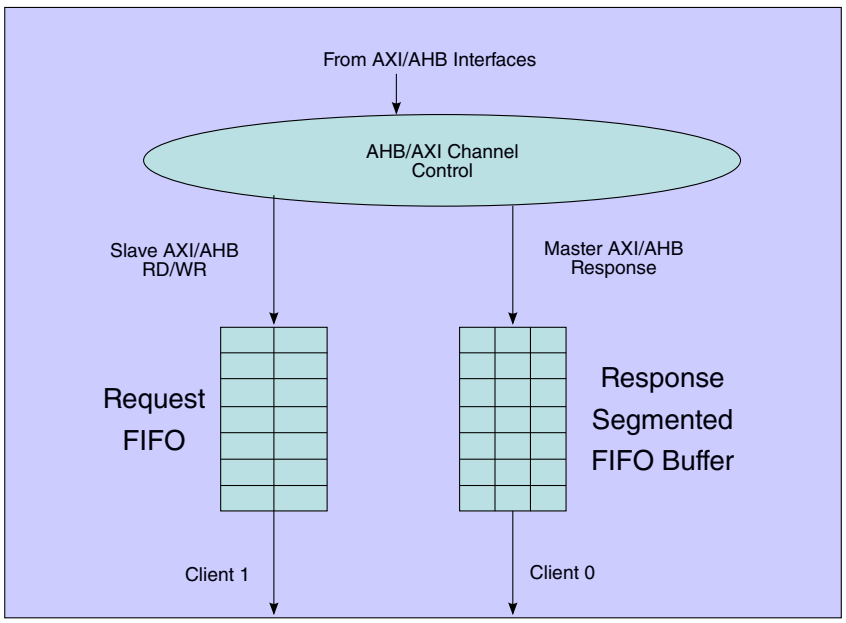

Figure 48-38. AXI Bridge Outbound Traffic Queuing Architecture

The native core (after the bridge) has no transmit buffering and requests and completions are transmitted onto the wire directly. Completions use a different interface (XALI0) to requests (XALI1) and may or may not pass the outbound requests depending on client arbitration.

48.4.2.6.4 PCIe Completion Reordering

If the returning completions (for all Non Posted outbound requests with the same AXI ID) from the remote device are returned out-of-order, the bridge Slave Response Composer will re-order them according to AXI IDs.

Only completions corresponding to outbound requests with the same AXI ID are re-ordered, while all others ones will be returned following the chronological order in with which they are received from the remote device.

48.4.2.6.5 Outbound Ordering Limitation #1

An outbound AXI request at the slave interface may be decomposed into multiple PCIe TLP requests.

See Decomposition for more information. There is a PCI Express protocol ordering rule that states that the completions associated with the different TLPs may pass each other. The current bridge Slave Response Composer design cannot handle this scenario and will not re-order the completions, resulting in data corruption. To avoid data corruption, one of the following workarounds is required.

- Prevent outbound decomposition by ensuring that your application master does not generate bursts of size greater than Max_Read_Request_Size. Otherwise, you must program or design your PCI Express system with a larger value of Max_Read_Request_Size. See Decomposition Side-Effects.
- Set AMBA Multiple Outbound Decomposed NP Sub-Requests Control Register to '0' which will disable the possibility of having multiple outstanding non-posted requests that were derived from decomposition of an AMBA request. This should only be done when decomposition is guaranteed to occur and completions are coming back out of order from the wire, as it restricts the PCIe transmit link performance by only having one outstanding non-posted request TLP (from a request that is being decomposed) on the PCIe link at any one time.

It is also a PCI Express ordering rule that a remote device which completes a single request using multiple completions (CplD) must return them in-order. The bridge can accept an interleaved stream of multiple completions (in response to multiple requests it originally transmitted), provided that all the completions for any one original request are in-order.

48.4.2.6.6 Outbound Ordering Limitation #2

Posted and non-posted AXI *writes* targeting the bridge slave must use different AXI tags in order to allow the relevant B-channel responses to be received in-order.

If this restriction is not observed, it can happen that a B-channel response to a posted (P) write (MWr/Msg) arrives before the B-channel response associated to a non posted (NP) write (for example, IOWr), even if the NP request send first.

The B-channel response to a P write is issued by the AXI bridge slave immediately after the request is accepted by the bridge slave. The B-channel response to an NP write is issued by the AXI bridge slave when the completion (CplD) arrives back from the remote link partner.

48.4.2.6.7 Additional Information (AXI bridge bandwidth)

Order enforcement through the native core is discussed in App Note: Order Enforcement Using the PCIe Core.

48.4.3 PCIe AXI Core Operations

48.4.3.1 AXI Sideband (Misc. Bus) Signals

An AXI sub-system can only convey data, address and read/write information. It has no way to propagate PCIe concepts such as TLP type, Posted/Non Posted, Function Number, TLP attributes and so on. Therefore, some method is required to map these PCIe concepts between AXI and PCIe. This is done through the Software option.

Use the Internal Address Translation (iATU) to map outbound AXI transactions from different AXI address regions to particular PCIe address regions and TLP types. For example, map all AXI transactions in the region 0x0010FD00 - 0x00FFFFFF to CFG TLPs in the PCIe address region 0xD010FD00 - 0xD0FFFFFF.

48.4.3.2 Supported AXI Transfer Type

The AXI Bridge Module is compliant with the AMBA 3.0 AXI specification.

48.4.3.3 Supported AXI Burst Operations

- For outbound transfers (accessing bridge SLAVE):
  - The AXI bridge slave supports the incremental burst type (INCR) which is used in conjunction with ARLEN and AWLEN to define any length of burst.
  - The AXI bridge slave does not support the WRAP and FIXED burst types. If your application issues these burst types to the AXI bridge slave, a SLVERR or DECERR response is not returned by the bridge slave. In this scenario, the PCIe core exhibits undefined behavior.
- For inbound transfers (using bridge MASTER):
  - The AXI bridge master used the incremental burst type (INCR) which is used in conjunction with ARLEN and WLEN to define any length of burst.
    - The parameter CC_MSTR_BURST_LEN controls the maximum length burst that will be generated by the master interface.
  - The AXI bridge master does not use the WRAP and FIXED burst types.

48.4.3.4 I/O and CFG Transaction Handling over AXI Bridge

I/O and CFG-type inbound and outbound transfers are fully supported by the AXI bridge. I/O and CFG transactions always have the following characteristics:

Table 48-29. IO and CFG Characteristics

A payload of length equal to one DWORD (four bytes, 32 bits).
First byte enable (FBE) can be any value including '0000'.

Table continues on the next page...

Table 48-29. IO and CFG Characteristics (continued)

A payload of length equal to one DWORD (four bytes, 32 bits).
Last byte enable (LBE) is always '0000'.

48.4.3.4.1 Outbound I/O and CFG Transaction Handling

The following conditions must be satisfied for all outbound CFG and I/O requests presented by the application to the bridge slave interface:

- The outbound IO/CFG transactions should be DWORD aligned. Therefore, slv_a*addr[1:0]=00b and slv_a*size=2.
- The outbound AXI -> PCIe transfer must complete in a single AXI transfer without the need for a bus burst or a series of bus transfers.
- The maximum burst length for outbound IO and CFG transfers is one, corresponding to one DWORD.

There is one methods that can be used to signal to the PCIe core that the application wants to send an IO or CFG transfer.

48.4.3.4.1.1 Method I: Address Translation Method of Sending an Outbound IO or CFG Transfer

The optional internal address translation unit (iATU) in the native core can change the TYPE of an outbound request from MEM to IO or CFG by matching the address of that request to a configured address range as set by the application. See Internal Address Translation (iATU).

NOTE

You should use the ìInternal Address Translation (iATU)î instead of the Slave Request Sideband Bus (slv_a*misc) - to transmit CFG or IO requests.

It is also possible to do the same (for READs only) using a customer defined external address translation unit.

48.4.3.4.2 Inbound I/O and CFG Transaction Handling

The inbound PCIe -> AXI transfer completes in a single transfer without the need for a burst or a series of transfers except during:

- NCBE transfer. e.g. FBE = 1011 | 0101 | 1001 | 1101.
- Unaligned[1] transfer. e.g. FBE = 1110 | 1100 | 1000
- Narrow transfer. e.g. FBE = 1110 | 1100 | 1000 | 0111 | 0011 | 0001

1.For an unaligned (i.e. non-DWORD aligned) inbound PCIe -> AXI transfer (FBE = 1110 | 1100 | 1000), the AXI transfer still completes in one bus beat since LBE = 0000.

48.4.4 Additional AXI Reference Material

48.4.4.1 AXI Decomposition Rules

The host software can program the PCIe device to support certain maximum write transfer sizes and maximum read request sizes.

The native PCIe core's configuration module contains the device's *Max_Payload_Size* and *Max_Read_Request* size information, which are defined by the application software. The AXI bridge supports mismatches that occur when the AXI maximum transfer length is different than the *Max_Payload_Size* and *Max_Read_Request* size. For example, an inbound read transfer has an associated response buffer that is dependent on the remote PCIe device's *Max_Read_Request* size. An inbound write transfer has a master write buffer that is dependent on the remote PCIe device's *Max_Payload_Size*.

48.4.4.1.1 Outbound Decomposition

Automatic segmentation and reassembly of outbound (application to PCIe wire) packets is performed to satisfy PCI Express *Max_Read_Request_Size* and *Max_Payload_Size* rules. When a decomposition rule is triggered, the outbound TLP is broken up into two or more smaller TLPs. If the TLP type is Non Posted then additional PCIe TAGs are used from the TAG pool. Additional entries in the outbound header buffer are also used.

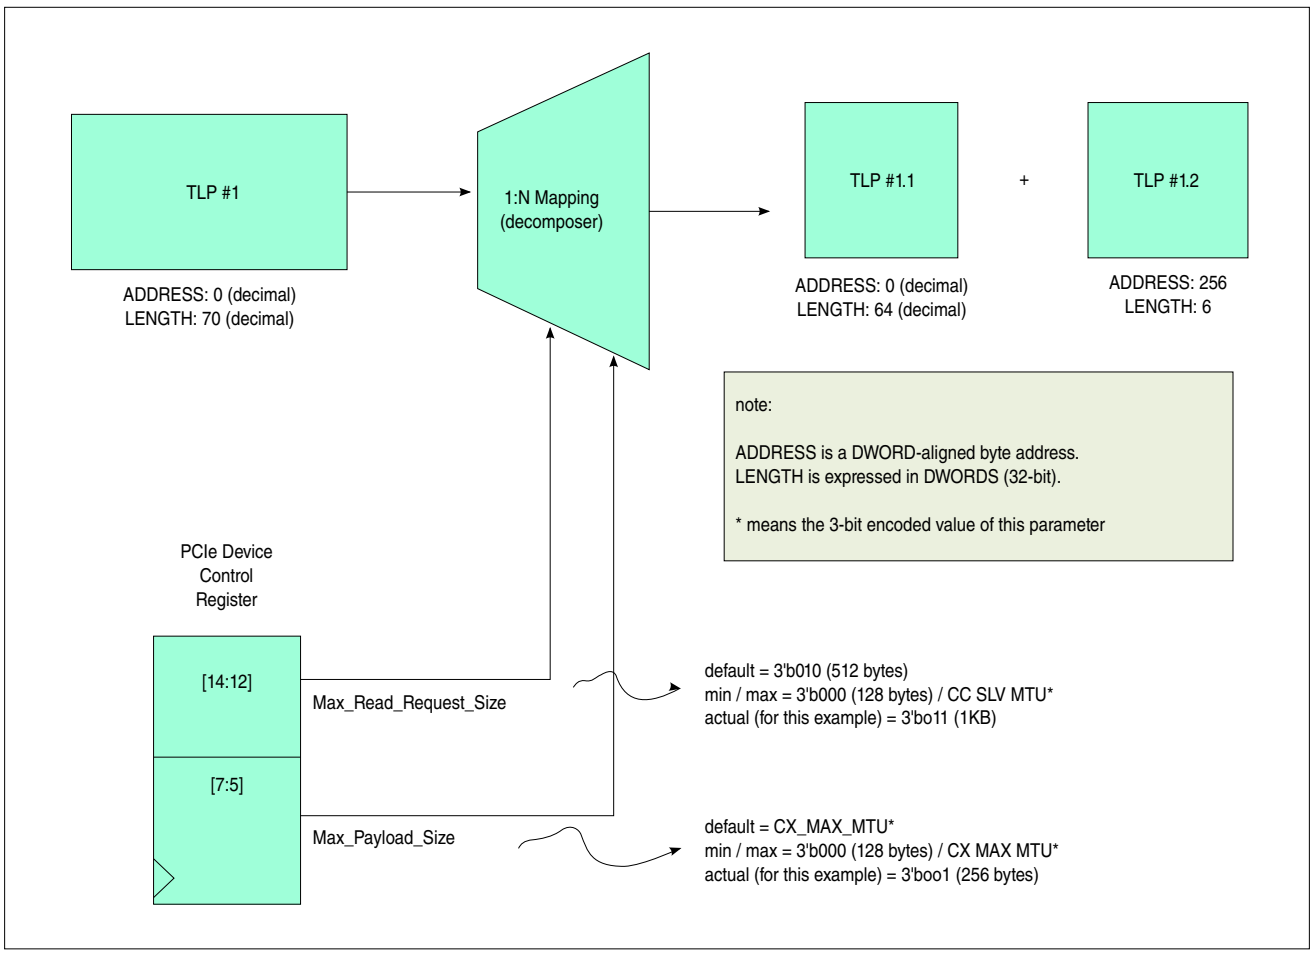

Figure 48-39. Outbound Decomposition Example of MemWr with Max Payload Size set to 256 bytes (64 DWORDs)

The Slave Request Decomposer module uses the following rules to determine when decomposing takes place.

Table 48-30. Outbound Decomposition Rules

TLP Request Type	Decompose[1] When
Read	TLP length >= PCIe Max_Read_Request_Size
Write	TLP length >= PCIe Max_Payload_Size

1. To avoid possible decomposition when the address is not DWORD aligned, you must ensure that TLP length is not only > Max_Read_Request_Size but also >= Max_Read_Request_Size.

The AXI page boundary is 4K, and so the application master request (at the AXI Slave Interface) will not issue a request that involves crossing a 4K PCIe page boundary - AXI protocol demands it.

NOTE

CX_MAX_MTU - 128

The largest packet payload (Maximum Transfer Unit) that the device will support. Specified in bytes and not DWORDS.

This is distinct from the maximum operating payload (Max_Payload_Size) which may be set by software.

48.4.4.1.1.1 Decomposition Side-Effects

Decomposition degrades the PCIe link performance as because it increases the amount of TLP header overhead and uses up extra PCIe TAGS.

Decomposition uses up extra header FIFO locations which will reduce the bridges bus-offloading ability in some cases.

48.4.4.1.1.2 Reducing Outbound Decomposition

To reduce decomposition on the outbound path, observe the following guidelines.

For Write Requests:

- Ensure that your application master does not generate bursts of size greater than or equal to Max Payload Size. In this context 'burst size' refers to the total number of bytes requested, or
- Program your PCI Express system with a larger value of Max_Payload_Size without exceeding CX_MAX_MTU (128).

For Read Requests:

- Ensure that your application master does not generate bursts of size greater than or equal to Max_Read_Request Size or,
- Program your PCI Express system with a larger value of Max_Read_Request without exceeding CC_SLV_MTU (128).

48.4.4.1.2 Inbound Decomposition

In a similar manner, automatic segmentation and reassembly of inbound packets is performed. The same AXI ID is used for all decomposed packets. The figure below illustrates the rules that are used in the Master Request Decomposer module to determine when decomposing takes place.

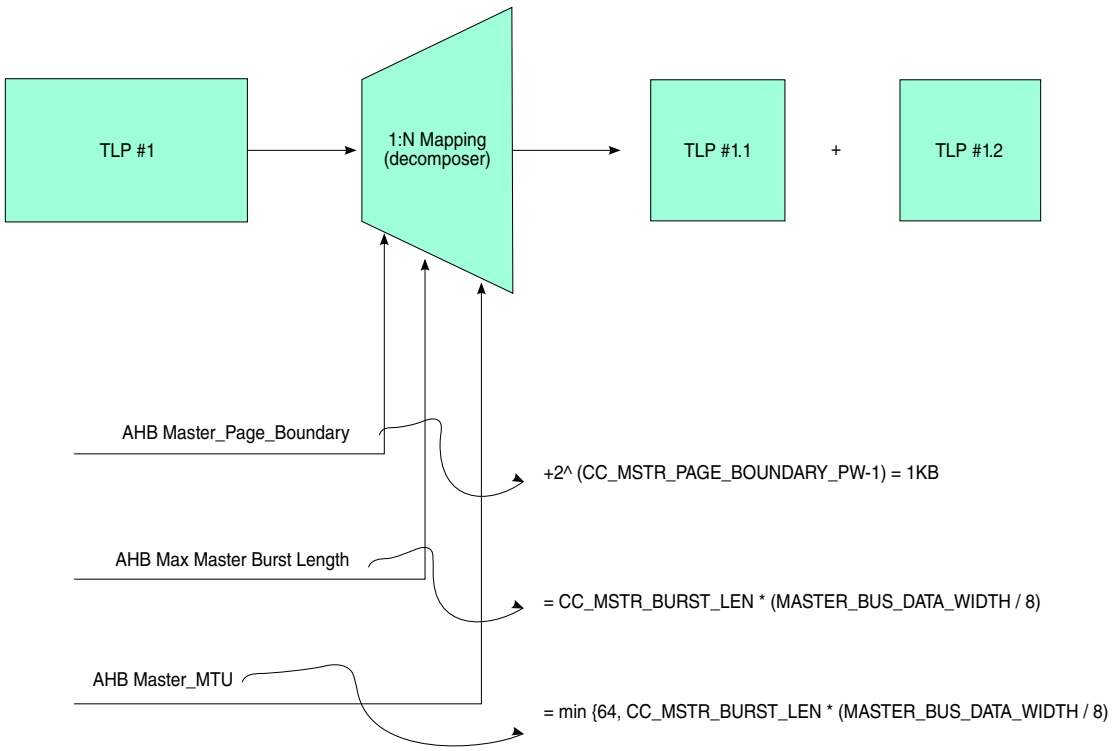

Figure 48-40. Inbound Decomposition

CC_MSTR_BURST_LEN (16) is the maximum burst in bus beats that the bridge will ever issue at the bridge master interface. It is set by the user.

The following rules are used in the Master Request Decomposer module to determine when decomposing takes place.

Table 48-31. Inbound Decomposition Rules

TLP Request Type	Decompose When
Read	TLP length (bytes) > AXI Master_Max_Read_Request_Size (see Figure 48-40)
Write	TLP length (bytes) > AXI Master_MTU (see Figure 48-40)
Read or Write	TLP address + TLP length crosses an AXI Master_Page_Boundary (see Figure 48-40)

The AXI *Master_Page_Boundary* specifies an address page boundary of 4K. The AXI bridge will ensure that the inbound request will not cross the selected page boundary when driven onto AXI master interface. .

48.4.4.1.2.1 Reducing Inbound Decomposition

To reduce decomposition on the inbound path, observe the following guidelines. For Read Requests:

- Ensure that the remote link partner does not issue a read request TLP with a requested length greater than the AXI *Master_Max_Read_Request Size* (see Figure 48-40).

or

- Design your application (and configure the bridge) to handle longer AXI bursts. That is, increase the value of the configuration parameter CC_MSTR_BURST_LEN or increase the AXI master data bus width.

For Write Requests:

- Ensure that the remote link partner does not issue a write request TLP with a payload greater than the AXI *Master_MTU* (see Figure 48-40).

or

- Design your application (and configure the bridge) to handle longer AXI bursts. That is, increase the value of the configuration parameter CC_MSTR_BURST_LEN or increase the AXI master data bus width.

For All Requests:

- Program or design your PCI Express system so that a TLP address plus the TLP length does not cross the AXI *Master_Page_Boundary* (see Figure 48-40).

.

48.5 App Note: Order Enforcement Using the PCIe Core

48.5.1 PCIe Ordering Rule Overview

This application note is written for applications that require certain ordering rules within PCIe traffic. There are many ordering rules according to the PCIe specification. The following is a general description from the PCIe 2.1. base spec.

PCIe 2.1 base specification defines the ordering requirements for PCI Express transactions. The ordering rules defined in the spec apply within a single traffic class (TC). There is no ordering requirement among transactions with different TC levels.

Root Complexes that support peer-to-peer operation and Switches must enforce these transaction ordering rules for all forwarded traffic. These forwarding devices should not forward traffic from one virtual channel to another.

Basic ordering rules are summarized as follows:

- Posted is permitted to pass posted transaction only if the relaxed order bit is set.
- Non-posted is permitted to pass or to be blocked by non-posted.
- Completion with different ID is permitted to pass or be blocked by other completions.
- Posted must be allowed to pass non-posted to avoid deadlock.
- Posted is permitted to be blocked by completions.
- Non-posted can never pass posted.
- Non-posted is permitted to pass or be blocked by completions.
- Completions can pass posted only if the relaxed order bit is set.
- Completions must be allowed to pass non-posted to avoid deadlock.

In general, ordering rules are used based on a specific device's functionality. Root Complexes with peer-to- peer support and switch devices must enforce the above rules. For endpoint devices, it is device-specific. For example, it is possible that an endpoint device is allowed to have completions passing posted and non- posted requests. Because most of the above rules are considered as "permitted or blocked", it is legal to have "permitted" or "blocked" be determined by the architecture of the PCIe core and AXI bridge. The DWC PCIe core and AXI bridge IP is designed such that the order rules may be enforced strictly or less strictly, based on the requirements of the application.

48.5.2 PCIe Core Inbound Order Enforcement

There are three receive queue architectures within the DWC PCIe core. These queue structures will determine different order enforcement based on different receive queue architectures.

If the core is configured with all transactions in bypass mode, then order enforcement should be performed by the application logic. The core will not be responsible for implementing PCIe order enforcement. Since it is an all bypass configuration, all transactions are presented onto the application interface in the order that they arrived.

Below are descriptions for different queueing architectures that are implemented in the PCIe IP core. Three different queue modes are configurable and are designed to suit different applications.

48.5.2.1 Single queue

In Single queue mode, a single header and data queue are populated in the DWC PCIe core for all transactions received. Completions can be bypassed if desired, based on the application. Single queue mode implements strong ordering (in order delivery). All transactions of the same or different traffic class are enqueued and dequeued in the order the transactions were received. For example, if a non-posted transaction is followed by a posted transaction, then the application interface (the DWC PCIe core's target1 interface) will have a non-posted transaction being presented, followed by a posted transaction. Even if the non-posted transaction is blocked by the application (halt), the posted transaction will not be allowed to bypass.

This queue mode has followed all ordering rules above except for rule #4 and rule #9 if completion is not in bypass. What this queuing mode implements is that posted transactions will be blocked by another posted, non-posted will be blocked by another non-posted, etc. That is, we have selected ìblockî as the default of the above ordering rules. According to the spec., these are permitted except for rule #4, and possibly rule #9, if the completion is not in bypass. Rule #4 and rule #9 exist to avoid deadlocks caused by credit starvation and are applicable only when the TLP will be forwarded to another PCI/PCIe link. Because of these violations, this queue mode is not appropriate for a Root Complex (with peer-to-peer support) or for switch designs. This is designed for endpoint devices that have no order rule requirement at the transaction forwarding between the DWC PCIe core receive queue and the core application interface. The advantage of this queue mode is that it is simple, resulting in an area and power advantage.

48.5.2.2 Multiple queue

In Multiple queue mode, a header and data queue per type of transaction are populated in the DWC PCIe core. All transactions are enqueued in-order. All posted are enqueued into posted header/data queue. All non-posted are enqueued into a header/data non-posted queue and all completions are enqueued into a header/data completion queue. In multiple VC cases, each VC will have its own set of queues.

This queue mode has the same ordering as for single-queue mode. The user has further flexibility in setting which TLPs are bypassed and which TLPs are added to the ordering queue, but these additional modes offer little practical value in the normal case. Since it shares the same limitations as singe-queue mode, this queue mode is not likely appropriate for a Root Complex with peer-to-peer support or for switch designs This queue has some gate count advantage over the full order support provided by the segmented buffer; however, this advantage is generally minor, especially for multi-VC systems.

48.5.2.3 Segmented buffer queue

A single header/data queue are populated in the DWC PCIe core for this queue mode. Transactions of different types are queued into a segmented buffer; each TLP type into a separate segment in the buffer. The transaction's order information is also queued into the segmented buffer. All posted requests are enqueued into the posted segment, all non-posted requests are queued into the non-posted segment and all completions are enqueued into the completion segment. Each traffic class also has its own dedicated per- type segments.

All PCIe order enforcement rules are strictly followed. All transactions are normally served in the order of reception, if the application has no blocking (halt) of the transactions received. If the application does have blocking conditions , then the order rules are enforced for transactions being read out of the queue. For example, if a non-posted request is received followed by a posted request, and the application could not take any more non-posted requests, then the posted will be allowed to pass the non-posted request and the posted transaction will be presented onto the application interface. In a second example, a posted request is received followed by a non-posted request, and the application can not take any more posted requests, then the non-posted transaction will be blocked even if the application can take the next non-posted transaction. Only when there are no previously received posted requests will the non-posted transaction be presented onto the application interface.

Since the order information is stored along with each transaction, full PCIe order enforcement can be accomplished through this mode of operation. This is the difference from the single and multiple queue architectures.

Segmented buffer queue mode is designed for Switches and Root Complexes with peer-to-peer support. The primary advantage of this mode is the full support of PCIe ordering rules. In addition, this mode offers a reduced RAM requirement when compared with multi-queue mode, especially for multi-VC designs.

The figure below represents the various queue architectures of the DWC PCIe IP core inbound receiving traffic. There are three different queue modes. As described above, the ordering rules are implemented differently, based on different queue architecture.

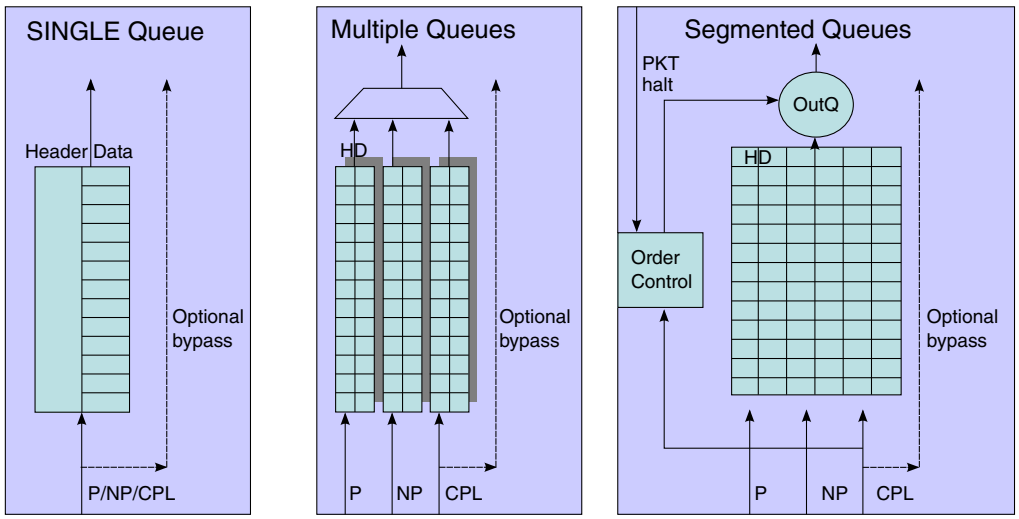

Figure 48-41. DWC PCIe Core Inbound Traffic Queue Architectures

48.5.3 PCIe Core Outbound Order Enforcement

The PCIe Core has a basic transmit architecture such that all transactions are presented outbound onto the PCIe wire based on the order the application presents them onto the PCIe core transmit interfaces.

There are up to three application outbound transmit interfaces (client0, client1 and optionally, client2). All client interfaces are served default as round robin arbitration if credit is available, regardless of the type of transaction. For example, if a posted transaction is presented onto client1 followed by a completion transaction, and if credits permit, then the posted transaction will be transmitted onto the wire before the completion. If the credit is not available, then the completion can pass the posted and be sent onto the wire.

It is the responsibility of the application to make appropriate use of the three client interfaces. An application that has three independent threads of traffic can use the three client interfaces such that the PCIe core will do the arbitration for the outbound transmission. For example, if the application has one source of outbound read transactions and one source of outbound write transactions, and they are independent sources, then client0 and client1 interfaces of the PCIe core should be used to perform the outbound transmission of the transactions. If the read and write are related, then one single interface client0 should be used and it is up to the application to maintain the desired order.

Most applications have independent threads of inbound reads such that its completion is not related to the outbound reads and writes. With these, an independent application interface such as client2 should be used for outbound completions.

In general, there is no transmit queuing in the PCIe core. Therefore, there is no order enforcement among outbound transactions within the transmit queue. The PCIe core has a cut-through transmit architecture where all outbound transaction order rules are enforced by the application. The PCIe core transmits TLPs in the order they are accepted by the core.

Endpoint devices can use two or three client interfaces for posted, non-posted and completion outbound traffic. The two or three client interfaces are determined by whether there is a dependency between the posted and non-posted traffic.

Root Complex and Switch devices will likely use one client interface where the order enforcement is performed by the application logic, where the outbound transfer queue is near to the transmit interface. The credit information is an output of the PCIe core, where it can be used as an input for taking outbound transactions out of the application's queue.

The figure below shows the outbound traffic queue architecture of the PCIe core. As shown in the figure, there is no transmit queue implemented in the core. There is just a retry buffer for replaying PCIe traffic as required by the PCIe base specification. Therefore, outbound TLPs will pass directly from the client interface through the core and to the wire in the same order they were accepted from the application.

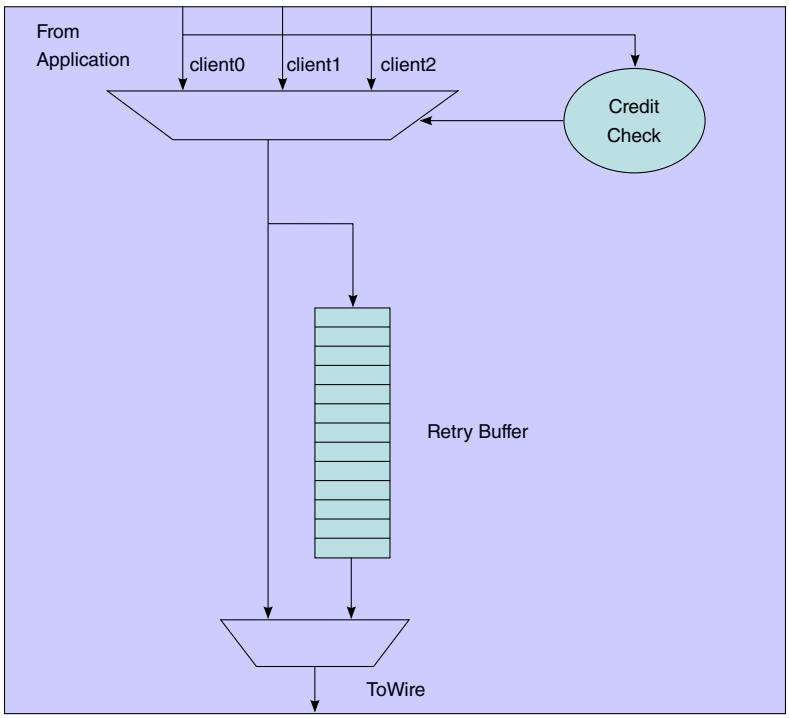

Figure 48-42. PCIe Core Outbound Traffic Queue Architectures

48.5.4 PCIe AHB/AXI Bridge Order Enforcement

Order enforcement through the AXI/AHB bridges is discussed in the following sections:

- Inbound Order Enforcement for AXI Bridge
- Additional Information (ordering)

48.5.5 Additional Information

Additional information is available at:

- Queuing Architecture.
- Queue Modes.
- Order Enforcement.

48.6 App Note: Calculating Gen1 PCI Express and AXI Bridge Throughput

This application note defines the throughput calculation (primarily) with respect to the PCI Express core in Gen1 2.5 GT/s mode.

NOTE

The max transfer size is 128bits

48.6.1 PCI Express Throughput

PCI Express bandwidth is 2.5 Gb/s (gigabits per second), per lane, when operating at the Gen 1 data rate. Because data is encoded using 8b10b encoding, the effective maximum throughput is 250 MB/s (megabytes per second), per lane (and overall throughput since we have 1 lane) , calculated as follows:

2.5 Gb * 8b/10b = 2 Gb * 1B/8b = 250 MB/sec per lane

48.6.2 Effective Throughput

The effective throughput is the payload throughput once all PCIe protocol's overheads have been factored out. The key protocol features are:

- 8b10b encoding at the physical layer. This takes away 20% of the raw bandwidth.
- Acknowledge and flow control update packets at the data link layer (DLLPs). This takes away 1% to 5% of the remaining bandwidth.
- Packet overhead at the transaction layer. Your design choices have a great effect here:
  - Small packets may take away 75% of the bandwidth!
  - Large packets may take away as little as 1%.

48.6.2.1 Effective Throughput Calculation

The table below identifies the TLP package.

Table 48-32. TLP Packet (with associated Data Link Layer overhead bytes)

STP 1 Byte	SEQ 2 Bytes	TLP Header 12/16 Bytes	Data Payload	ECRC 4 Bytes	LCRC 4 Bytes	END 1 Byte

48.6.2.1.1 Packet Level: (Start and End, Link CRC, Header)

The table below summarizes throughput calculations based on a payload size from 16 to 4K bytes.

Table 48-33. Effective Throughput

	Payload Bytes	Header Bytes	ECRC Bytes	PHY and Data Link Layer Bytes	Calculation	Percent Throughput	Note
Worst Packet	16	16	4	8	16/44	36%	Has ECRC.
Typical Packet	128	16	0	8	128/152	84%	No ECRC.
Typical Packet	256	16	0	8	256/280	91%	No ECRC.
Typical Packet	512	16	0	8	512/536	96%	No ECRC.
Best Packet	4096	12	0	8	4096/4116	99%	No ECRC.

NOTE

A 128-byte payload size yields about 67% of the net throughput. Increasing the payload size to 512 bytes increases the net throughput to 92%. Increasing the payload size from 512 bytes to 4096 bytes only contributes an increase of 8% in the net throughput, and the storage requirements are more than doubled. In addition, a large payload size may have an impact on performance due to re- transmission of TLPs. Therefore, 256-byte and 512-byte payload sizes are the most popular choices. Most chipsets support 128 -byte or 256-byte payload sizes, with 512 bytes gaining in popularity.

48.6.2.1.2 Link Layer: (Flow Control and ACK/NAK DLLPs)

DLLPs should be sent as often as required to avoid a negative impact on the TLP throughput. The core sends a pending DLLP if there is no competing TLP traffic.

Sending ACK/NAK and Update FC is controlled by timers. The core provides flexibility to fine-tune these as required. The default setup is minimal flow control (one per time-out) and minimal ACK/NAK device latencies. The link partners retry buffer (payload) size may require a change in the ACK/NAK/Update FC time-out to obtain optimal system latencies.

The core provides a feature to accumulate up to 255 ACKs before issuing an ACK. This feature offers-fine tuning of ACK frequency impact. The core transmits ACKs at fixed intervals, by default.

The following table identifies the DLLP package.

Table 48-34. DLLP Package

STP	Type	Data	16b CRC	END
1 Byte	1 Byte	4 Bytes	2 Bytes	1 Byte

The following table summarizes the throughput calculations.

Table 48-35. Effective Throughput

	Bytes	Result	Percent Throughput
Worst Packet	One ACK plus one FC per 128 (8 packets of 16) bytes of data => 2 DLLPs per 8 data packets	(8*44) / (8*44 + 2*8)	95%
Typical Packet	One ACK plus one FC per 1.4 (256 byte payload) bytes of data => 2 DLLPs per 1.4 packets	1.4*280 / (1.4*280 + 2*8)	96%
Best Packet	One ACK plus one FC per 4096 bytes of data => 2 DLLP per data packet	4116 / (4116 + 2*8)	99%

48.6.2.2 Other Factors Impacting Throughput

Replay buffer and receiver queue sizing should be optimal to avoid a harmful impact of larger ACK/NAK or Update FC latencies by the link partner. The core does a very effective autosizing of the buffers taking into consideration the impact of these parameters.

Effective Throughput (ET) = Raw Throughput * (NL x 2.5 Gb)

Consideration of lane width and payload size results in the following:

Table 48-36. Consideration of lane width and payload size

Factor	Throughput
8b10b	*(80%)
Link Packet	*(95% to 99%)
Data Payload	*(36% to 99%)

The table below identifies lane width and payload vs. throughput.

Table 48-37. Lane Width and Payload vs. Throughput

	Real Throughput Gb/s vs. Data Payload			
Lane Width	16	128	256	4096
x1	0.5	1.7	1.7	2.0

48.7 PCIe Registers (EP mode)

Information found here describes the core implementation of the PCI Express configuration space in the core in EP mode.

48.7.1 Register Space Layout (EP mode)

The core has 4096 bytes of PCI Express configuration space per function.

For each function, the PCI Express configuration space is divided into:

- 256 bytes of PCI Configuration Space, containing:
- 64 bytes of PCI 3.0 Compatible Configuration Space Header (type 0 in EP mode)
- PCI Standard Capabilities Structures linked list, which can start anywhere after offset 0x40
- 3840 bytes of PCI Express Extended Configuration Space (which starts at offset 0x100), containing:
- PCI Express Extended Capabilities Structures linked list, which starts at offset 0x100
- Port Logic registers (vendor-specific registers), which start at offset 0x700. The Port Logic registers have specific pre-defined usages, mostly for test purposes, and can optionally be removed from the core hardware configuration. The usage of the Port Logic registers is the same in both EP mode and RC mode. See PCIe Registers: Port Logic for details.

The figure below shows the EP mode layout of the core configuration space.

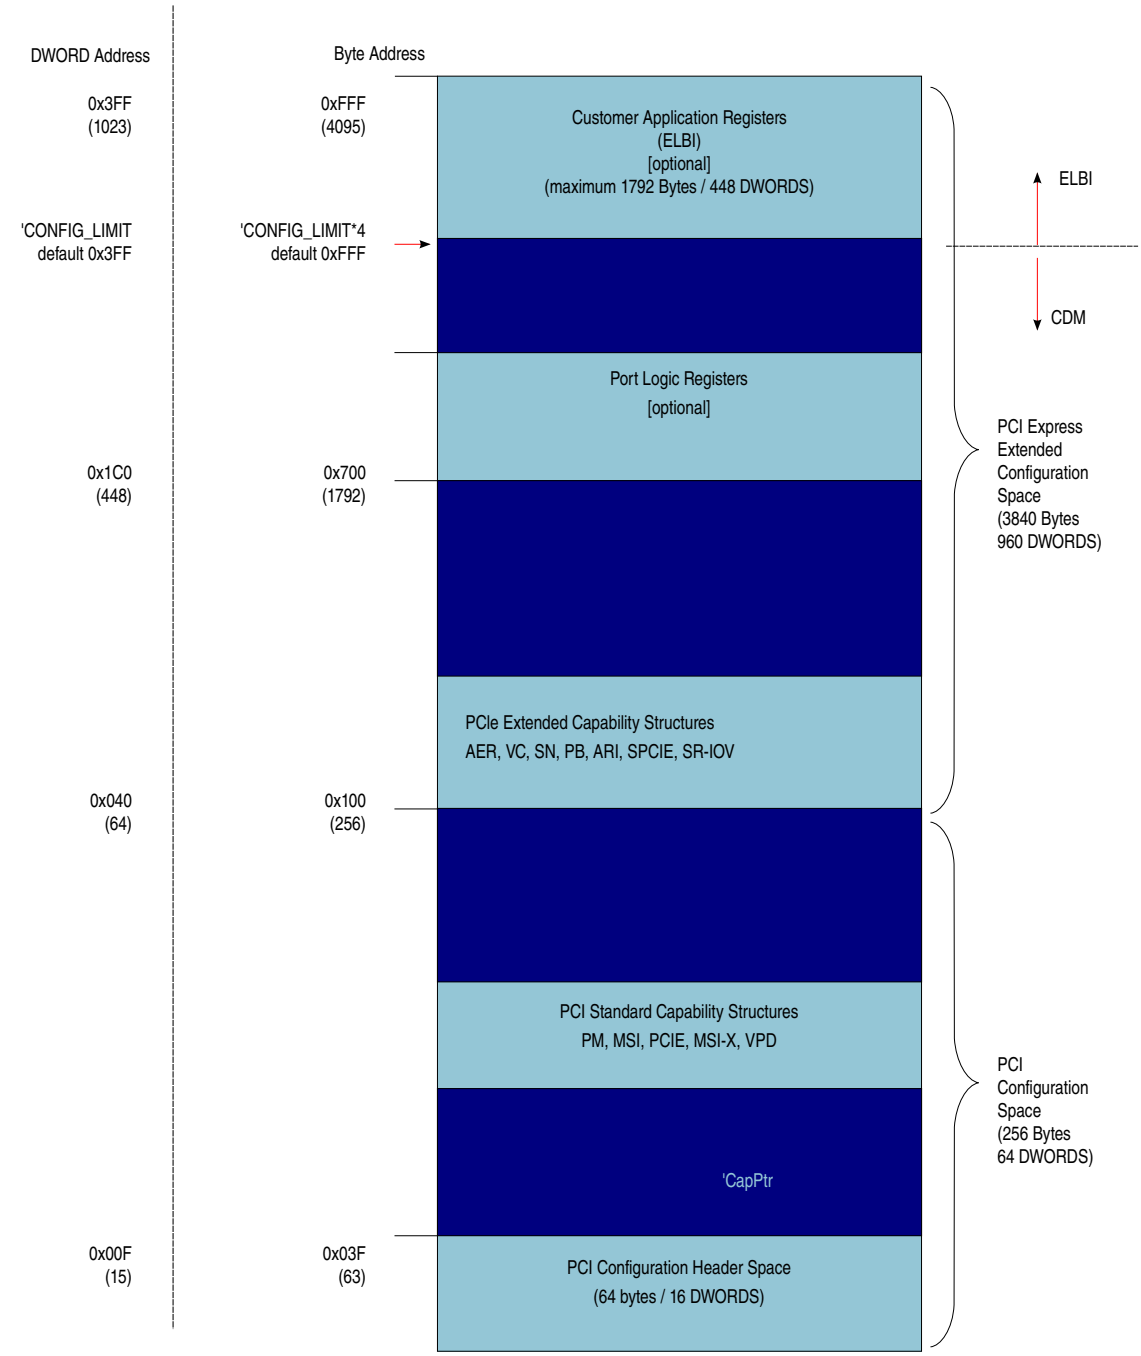

Figure 48-43. Core Configuration Space Layout (EP Mode)

48.7.2 PF Register Maps

Capability configuration registers are in structures (groups) identified by a Capability ID.

Groups are linked together as in PCI. Register locations within a group are specified, but the starting location of each group must be found by traversing the linked list. There are two linked lists of register groups: PCI Compatible Capability registers and PCI Express Extended Capability registers. PCI Compatible Capability register groups begin at the configuration address stored in the capability pointer register at 0x34. PCI Express Extended Capability register groups begin at address 0x100.

48.7.2.1 PF PCI Configuration Space Header - Type 0

The table below shows the layout of the Type 0 Configuration Space Header. Most PCI-compatible register fields have the same software interpretation in PCI 3.0 and PCI Express.

Table 48-38. PF PCI Configuration Space Header - Type 0

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x00	Device ID		Vendor ID	
0x04	Status Register		Command Register	
0x08	Class Code			Revision ID
0x0C	BIST(0x00)	Header Type	Latency Timer	Cache Line Size
0x10	Base Address Register 0			
0x14	Base Address Register 1			
0x18	Base Address Register 2			
0x1C	Base Address Register 3			
0x20	Base Address Register 4			
0x24	Base Address Register 5			
0x28	CardBus CIS Pointer			
0x2C	Subsystem ID		Subsystem Vendor ID	
0x30	Expansion ROM Base Address			
0x34	Reserved			CapPtr
0x38	Reserved			
0x3C	Max_Latency[1]	Min_Grant[1]	Interrupt Pin	Interrupt Line

1. The Max_Latency and Min_Grant registers do not apply to PCI Express and are read-only registers with values hardwired to 0x00.

48.7.2.2 PF PCI Standard Capability Structures Register Maps

The Capability Pointer register in the PCI-compatible header register points to the next item in the linked list of capabilities, which, by default, is the PCI Power Management capabilities register space.

NOTE

Even though there is an unique standard capabilities linked lists provided per function, specific capabilities cannot be enabled/disabled on a per-function basis; for example, MSI-X capability is enabled/disabled for all functions (PF) at the same time through the coreConsultant GUI.

NOTE

Each function (PF) may have a different configuration of that capability structure once it is enabled, although some features/settings are common across all functions.

The following tables list the capabilities supported by the core and their respective default address offsets and next capability pointers and provides the default values of the default address offsets.

Table 48-39. PF Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 0)	
0x40	PCI Power Management	
0x50	Message Signaled Interrupt (MSI)	
0x70	PCI Express Capabilities	

Table 48-40. PF Default Values of Parameters that Define Starting Addresses

Parameter	Default Value
CFG_PM_CAP	8'h40
CFG_MSI_CAP	8'h50
CFG_PCIE_CAP	8'h70

The following tables show the PCI Standard Capability Structures.

Table 48-41. PF Power Management Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x40	Power Management Capabilities (PMC)		Next Capability Pointer (PM_NEXT_PTR)	Capability ID (0x01)
+0x4	Data	PMCSR_BSE Bridge Extensions	Power Management Control Status Register (PMCSR)	

Table 48-42. PF MSI Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x50	Message Control Register		Next Capability Pointer (MSI_NEXT_PTR)	Capability ID (0x05)
+0x4	MSI Lower 32-bit Address Register			
+0x8	MSI Upper 32-bit Address Register			
+0xC	Reserved		MSI Data	
+0x10	Mask Bits Register			
+0x14	Pending Bits Register			

Table 48-43. PF PCI Express Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x70	PCI Express Capabilities Register		Next Capability Pointer (PCIE_NEXT_PTR)	Capability ID (0x10)
+0x4	Device Capabilities			
+0x8	Device Status		Device Control	
+0xC	Link Capabilities			
+0x10	Link Status		Link Control	
+0x24	Device Capabilities 2			
+0x28			Device Control 2	
+0x2C	Link Capabilities 2			
+0x30	Link Status 2		Link Control 2	

48.7.2.3 PF PCI Express Extended Capability Register Maps

The PCI Express Extended Capabilities registers are located in device configuration space at offsets 0x100 or higher. As with PCI Standard Capability Structures, the PCI Express Extended Capability structures are allocated using a linked list with a similar method and format to those of PCI.

NOTE

Even though there is a unique extended capabilities linked list provided per function, specific capabilities cannot be enabled/disabled on a per function basis.

NOTE

Each function (PF) may have a different configuration of that capability structure once it is enabled, although some features/settings are common across all functions.

The Advanced Error Reporting (AER) Capability and Virtual Channel (VC) Capability are optional extended capabilities that may be implemented by PCI Express devices supporting advanced error control and reporting and multiple VCs, respectively. The Advanced Error Reporting Capability is required when the device supports ECRC generation/checking. The Virtual Channel Capability is required for any device that supports multiple VCs and/or multiple Traffic Classes (TCs).

The Next Capability Pointer register in the PCI Express Extended Capability Structures Register Maps points to the next item in the linked list of capabilities, which, by default, is the Advanced Error Reporting (AER) Capability register space.

The table below lists the extended capabilities supported by the core and their respective default address offsets and next capability pointers.

Table 48-44. PF Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 0)	
0x100	Advanced Error Reporting	
0x140	Virtual Channel	

The following tables outline the PCI Express Extended Capabilities structures.

Table 48-45. PF Advanced Error Reporting (AER) Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x100	AER Extended Capability Header			
+0x4	Uncorrectable Error Status Register			
+0x8	Uncorrectable Error Mask Register			
+0xC	Uncorrectable Error Severity Register			
+0x10	Correctable Error Status Register			
+0x14	Correctable Error Mask Register			
+0x18	Advanced Error Capabilities and Control Register			
+0x1C through +0x28	Header Log Registers			

Table 48-46. PF Virtual Channel Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x140	Virtual Channel Extended Capability Header			
+0x4	Port VC Capability Register 1			
+0x8	Port Capability Register 2			
+0xC	Port VC Status Register		Port VC Control Register	

Table continues on the next page...

Table 48-46. PF Virtual Channel Capability Structure (continued)

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
+0x10	VC Resource Capability Register (0)			
+0x14	VC Resource Control Register (0)			
+0x18	VC Resource Status Register (0)		RsvdP	
0x10+(N*0x0C)	VC Resource Capability Register (N)[1]			
0x14+(N*0x0C)	VC Resource Control Register (N)			
0x18+(N*0x0C)	VC Resource Status Register (N)		RsvdP	

1. There is one VC Resource Capability/Control/Status Register N set for each configured VC (in addition to VC0).

1. Depends on the number of VCs

48.7.3 VF Register Maps

Similar to PFs, VFs also have Type 0 Configuration Space Header, a linked list of PCI Compatible Capabilities and a linked list of PCI Express Extended Capabilities.

The following PCI Compatible Capabilities are supported for VFs: P.

48.7.3.1 VF PCI Configuration Space Header - Type 0

The table below shows the layout of the Type 0 Configuration Space Header for Virtual Functions.

Table 48-47. VF PCI Configuration Space Header - Type 0

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x00	Device ID		Vendor ID	
0x04	Status Register		Command Register	
0x08	Class Code			Revision ID
0x0C	BIST(0x00)	Header Type	Latency Timer	Cache Line Size
0x10	Base Address Register 0			
0x14	Base Address Register 1			
0x18	Base Address Register 2			
0x1C	Base Address Register 3			
0x20	Base Address Register 4			
0x24	Base Address Register 5			
0x28	CardBus CIS Pointer			

Table continues on the next page...

Table 48-47. VF PCI Configuration Space Header - Type 0 (continued)

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x2C	Subsystem ID		Subsystem Vendor ID	
0x30	Expansion ROM Base Address			
0x34	Reserved			CapPtr
0x38	Reserved			
0x3C	Max_Latency[1]	Min_Grant[1]	Interrupt Pin	Interrupt Line

1. The Max_Latency and Min_Grant registers do not apply to PCI Express and are read-only registers with values hardwired to 0x00.

48.7.3.2 VF PCI Standard Capability Structures Register Maps

NOTE

All VFs have the same linked list of capabilities.

The Capability Pointer register in the Type 0 Header points to the next item in the linked list of capabilities, which, by default, is the PCI Express Capability.

The tables below list the VF standard capabilities supported by the core and their respective default address offsets and next capability pointers and provides the default values of the default address offsets.

Table 48-48. VF Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 0)	0x70
0x70	PCI Express Capability	0x00

Table 48-49. VF Default Values of Parameters that Define Starting Addresses

Parameter	Default Value
`CFG_PCIE_CAP	8'h70

The table below shows the VF PCI Express Capability Structure.

Table 48-50. VF PCI Express Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x70	PCI Express Capabilities Register		Next Capability Pointer 0x0	Capability ID (0x10)
+0x4	Device Capabilities

+0x30	Link Status 2		Link Control 2	

48.7.4 Accessing Configuration Registers

The application can access the configuration space through the DBI. Bits [11:0] of the DBI address bus select the target register.

Host software accesses the configuration registers through PCI Express Configuration Requests.

The Attribute (Attr) column in each register description indicates the read/write access for the register or bit. The table below defines the read/write attribute abbreviations that are used in the register and bit descriptions throughout this chapter.

Table 48-51. Configuration Register Bit-Field Types

Attribute	Description
HwInit	Hardware Initialized HwInit bits are controlled by core hardware and are read-only (RO) by host system software. These bits can only be reset with cold reset. They are not modified by an FLR, or by a warm or hot reset.
RO	Read-Only Register bits are read-only and cannot be altered by software. Register bits are permitted to be initialized by core hardware.
RW	Read-Write Register bits are read-write and may be read and written normally by the host and the application. Writing from the application side (if any) requires careful synchronization with the host software.
RW1C	Read-Only Status/Write-1-to-Clear Status Register bits indicate status when read. A set bit indicates a status event may is cleared by writing a 1. Writing 0 to RW1C bits has no effect. Writing from the application side (if any) requires careful synchronization with host software.

Table continues on the next page...

Table 48-51. Configuration Register Bit-Field Types (continued)

Attribute	Description
ROS	Sticky Read-Only Register bits are read-only and cannot be altered by host or application software, except as noted. Registers are not initialized or modified by a hot reset or FLR. A few bits designated as very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RWS	Sticky Read-Write Register bits are read-write and are set or cleared by host or application software to the desired state. Bits are not initialized or modified by a hot reset or FLR. A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RW1CS	Sticky Read-Only Status/Write-1-to-Clear Status Register bits indicate status when read. A set bit indicates a status event which is cleared by writing a 1, except as noted. Writing 0 to RW1CS bits has no effect. Bits are not initialized or modified by a hot reset or FLR. A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RsvdP	Reserved and Preserved Reserved for future RW implementations. Registers are read-only and return zero when read. Software must preserve the value read when writing to other bits in the same register.
RsvdZ	Reserved and Zero Reserved for future RW1C implementations. Registers are read-only and return zero when read. Software must write 0 to these bits when writing to other bits in the same register.
PF	Physical Function Indicates that this Virtual Function (VF) register bit inherits it's value from the corresponding parent Physical Function.

Most of the these registers are in the non-sticky reset domain. Non-sticky registers should be reset after a cold, warm or hot reset. .

48.8 PCIe Registers (RC mode)

Information found here describes the core implementation of the PCI Express configuration space when in RC mode.

Register definition applies to all cases unless otherwise specified.

48.8.1 Register Space Layout

The core has 4096 bytes of PCI Express configuration space per function.

For each function, the PCI Express configuration space is divided into:

- 256 bytes of PCI Configuration Space, containing:
- 64 bytes of PCI 3.0 Compatible Configuration Space Header (type 1)
- PCI Standard Capabilities Structures linked list, which can start anywhere after offset 0x40
- 3840 bytes of PCI Express Extended Configuration Space (which starts at offset 0x100), containing:
- PCI Express Extended Capabilities Structures linked list, which starts at offset 0x100
- Port Logic registers (vendor-specific registers), which start at offset 0x700. The Port Logic registers have specific pre-defined usages, mostly for test purposes, and can optionally be removed from the core hardware configuration. The usage of the Port Logic registers is the same in both EP mode and RC mode. See PCIe Registers: Port Logic for details.

The figure below shows the layout of the core configuration space.

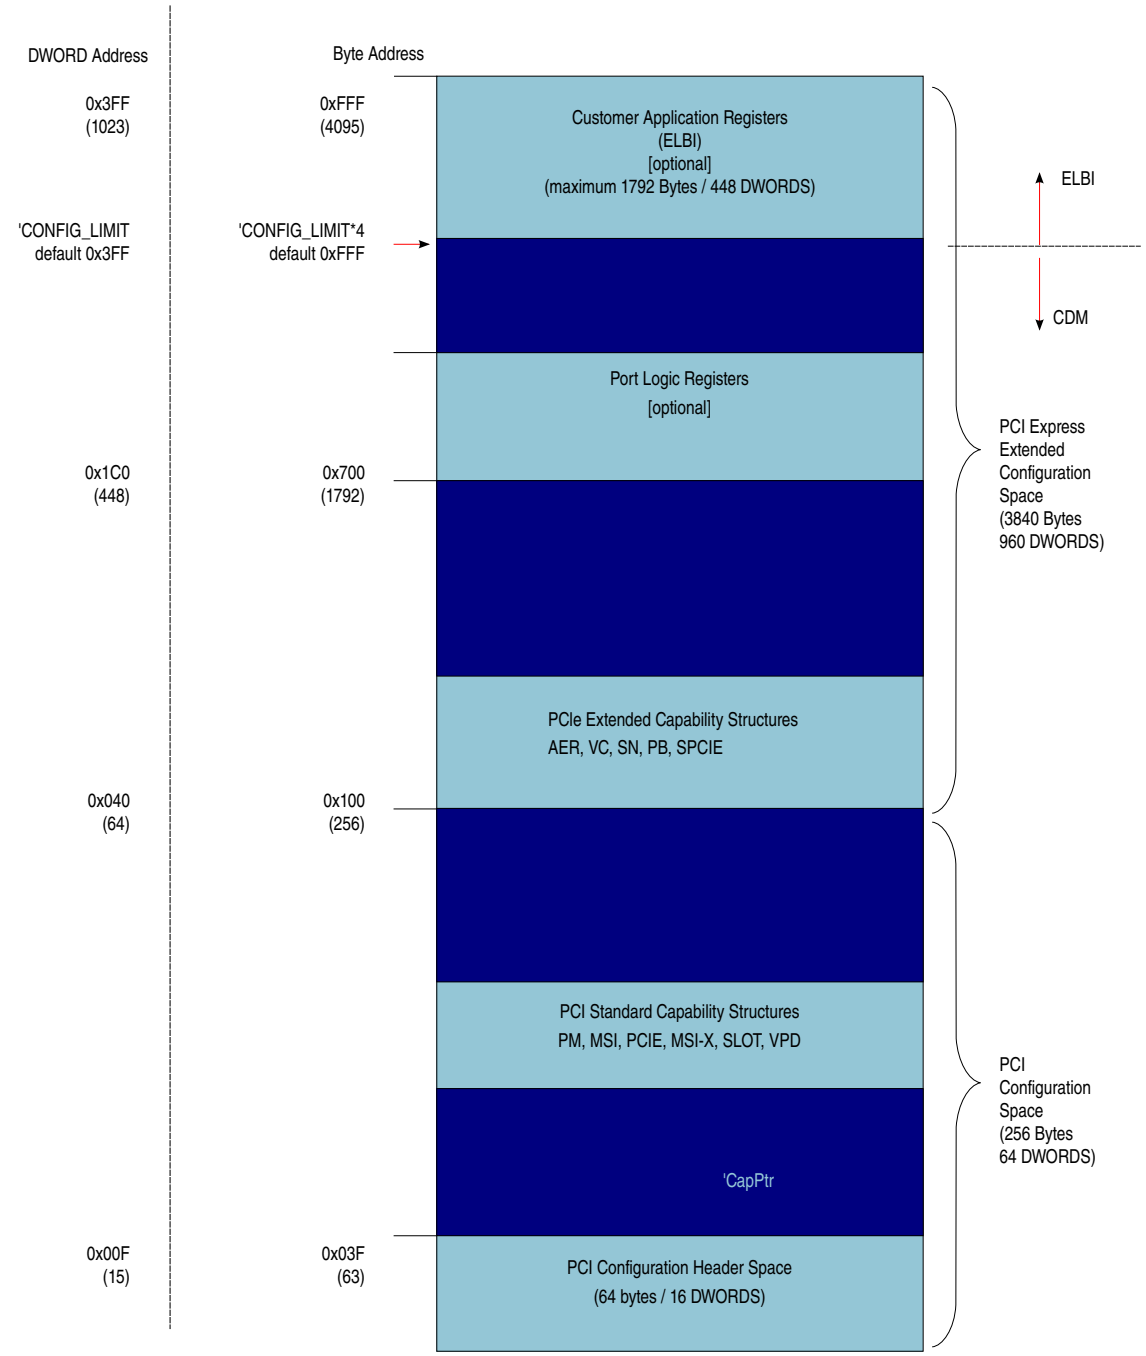

Figure 48-44. Core Configuration Space Layout: (RC Mode)

48.8.2 Register Maps

Configuration registers are in structures (groups) identified by a Capability ID. Groups are linked together as in PCI.

Register locations within a group are specified, but the starting location of each group must be found by traversing the linked list. There are two linked lists of register groups: PCI-compatible base registers and PCI Express Extended Capability registers. PCI-compatible base register groups begin at configuration address stored in capability pointer register at 0x34. PCI Express Extended Capability register groups begin at address 0x100.

Table below shows the configuration field register definitions for PCI Express Type 1 Configuration Space header. Most PCI-compatible register fields have the same software interpretation in PCI 3.0 and PCI Express.

Table 48-52. PCI Configuration Space Header - Type 1

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x00	Device ID		Vendor ID	
0x04	Status Register		Command Register	
0x08	Class Code			Revision ID
0x0C	BIST(0x00)	Header Type	Latency Timer	Cache Line Size
0x10	Base Address Register 0			
0x14	Base Address Register 1			
0x18	Secondary Latency Timer	Subordinate Bus Number	Secondary Bus Number	Primary Bus Number
0x1C	Secondary Status		I/O Limit	I/O Base
0x20	Memory Limit		Memory Base	
0x24	Prefetchable Memory Limit		Prefetchable Memory Base	
0x28	Prefetchable Base Upper 32 Bits			
0x2C	Prefetchable Limit 32 Upper Bits			
0x30	I/O Limit Upper 16 Bits		I/O Base Upper 16 Bits	
0x34	Reserved			CapPtr
0x38	Expansion ROM Base Address			
0x3C	Bridge Control		Interrupt Pin	Interrupt Line

48.8.2.1 PCI Standard Capability Structures Register Maps

The Capability Pointer register in the PCI-compatible header register points to the next item in the linked list of capabilities, which, by default, is the PCI Power Management capabilities register space.

Even though there is an unique standard capabilities linked lists provided per function, specific capabilities cannot be enabled/disabled on a per-function basis; for example, MSI-X capability is enabled/disabled for all functions at the same time through the coreConsultant GUI.

Each function may have a different configuration of that capability structure once it is enabled, although some features/settings are common across all functions.

Table below lists the capabilities supported by the core and their respective default address offsets and next capability pointers. Table 48-54 provides the default values of the default address offsets.

Table 48-53. Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 1)	
0x40	PCI Power Management	
0x50	Message Signaled Interrupt (MSI)	
0x70	PCI Express Capabilities	

Table 48-54. Default Values of Parameters that Define Starting Addresses

Parameter	Default Value
CFG_PM_CAP	8'h40
CFG_MSI_CAP	8'h50
CFG_PCIE_CAP	8'h70

The following tables show the PCI Standard Capability structures.

Table 48-55. Power Management Capability Structure

+0x38	Slot Status 2		Slot Control 2	
1. Slot Capabilities apply only to downstream ports; for example, RC.				

48.8.2.2 PCI Express Extended Capability Register Maps

The PCI Express Extended Capabilities registers are located in device configuration space at offsets 0x100 or higher. As with PCI Capabilities, the PCI Express Extended Capability structures are allocated using a linked list with a similar method and format to those of PCI.

Even though there is a unique extended capabilities linked list provided per function, specific capabilities cannot be enabled/disabled on a per function basis.

Each function may have a different configuration of that capability structure once it is enabled, although some features/settings are common across all functions.

The Advanced Error Reporting Capability and Virtual Channel Capability are optional extended capabilities that may be implemented by PCI Express devices supporting advanced error control and reporting and multiple VCs, respectively. The Advanced

Error Reporting Capability is required when the device supports ECRC generation/ checking. The Virtual Channel Capability is required for any device that supports multiple VCs and/or multiple Traffic Classes (TCs).

The Next Capability Pointer register in the PCI Express Extended Capability Structures Register Maps points to the next item in the linked list of capabilities, which, by default, is the Advanced Error Reporting (AER) Capability register space.

Table below lists the capabilities supported by the core and their respective default address offsets and next capability pointers.

Table 48-58. Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 1)	0x100
0x100	Advanced Error Reporting	
0x140	Virtual Channel	

The following tables outline the PCI Express Extended Capabilities structures.

Table 48-59. Advanced Error Reporting Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x100	PCI Express Extended Capability Header			
+0x4	Uncorrectable Error Status Register			
+0x8	Uncorrectable Error Mask Register			
+0xC	Uncorrectable Error Severity Register			
+0x10	Correctable Error Status Register			
+0x14	Correctable Error Mask Register			
+0x18	Advanced Error Capabilities and Control Register			
+0x1C through +0x28	Header Log Registers

+0x18	VC Resource Status Register (0)	RsvdP
0x10+(N*0x0C)	VC Resource Capability Register (N)1	
0x14+(N*0x0C)	VC Resource Control Register (N)	
0x18+(N*0x0C)	VC Resource Status Register (N)	RsvdP

1. There is one VC Resource Capability/Control/Status Register N set for each configured VC (in addition to VC0).

48.8.3 Accessing Configuration Registers (Configuration)

>The application can access the configuration space through the DBI. Bits [11:0] of the DBI address bus select the target register.

The Attribute column in each register description indicates the read/write access for the register or bit. Table below defines the read/write attribute abbreviations that are used in the register and bit descriptions throughout this chapter. The definitions match the PCI Express 3.0 Specification; in the case of a Root Port, all accesses are through the DBI so the host-access information does not apply.

Table 48-61. Configuration Register Bit-Field Types

Attribute	Description
HwInit	Hardware Initialized HwInit bits are controlled by core hardware and are read-only (RO) by host system software. Some HwInit bits are writable from the application through the DBI (if `CX_DBI_RO_WR_EN = 1), as indicated in the register descriptions. If `CX_DBI_RO_WR_EN = 0, none of the HwInit bits are writable through the DBI. These bits can only be reset with cold reset. They are not modified by an FLR, or by a warm or hot reset.
RO	Read-Only Register bits are read-only and cannot be altered by software. Register bits are permitted to be initialized by core hardware. Some RO bits are writable from the application through the DBI (if `CX_DBI_RO_WR_EN = 1), as indicated in the register descriptions. If `CX_DBI_RO_WR_EN = 0, none of the RO bits are writable through the DBI.
RW	Read-Write Register bits are read-write and may be read and written normally by the host and the application. Writing from the application side (if any) requires careful synchronization with the host software.

Table continues on the next page...

Table 48-61. Configuration Register Bit-Field Types (continued)

RW1C	Read-Only Status/Write-1-to-Clear Status Register bits indicate status when read. A set bit indicates a status event may is cleared by writing a 1. Writing 0 to RW1C bits has no effect. Writing from the application side (if any) requires careful synchronization with host software.
ROS	Sticky Read-Only Register bits are read-only and cannot be altered by host or application software, except as noted. Registers are not initialized or modified by a hot reset or FLR. A few bits designated as very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RWS	Sticky Read-Write Register bits are read-write and are set or cleared by host or application software to the desired state. Bits are not initialized or modified by a hot reset or FLR. A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RW1CS	Sticky Read-Only Status/Write-1-to-Clear Status Register bits indicate status when read. A set bit indicates a status event which is cleared by writing a 1, except as noted. Writing 0 to RW1CS bits has no effect. Bits are not initialized or modified by a hot reset or FLR. A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RsvdP	Reserved and Preserved Reserved for future RW implementations. Registers are read-only and return zero when read. Software must preserve the value read when writing to other bits in the same register.
RsvdZ	Reserved and Zero Reserved for future RW1C implementations. Registers are read-only and return zero when read. Software must write 0 to these bits when writing to other bits in the same register.
PF	Physical Function Indicates that this Virtual Function (VF) register bit inherits it's value from the corresponding parent Physical Function.

Some RO bits are writable from the application through the DBI

Most of the these registers are in the non-sticky reset domain. Non-sticky registers should be reset after a cold, warm or hot reset.

48.9 PCIe Registers: Port Logic

Information found here describes the Port Logic register map and the usage of each Port Logic register.

48.9.1 Overview (Port Logic)

The Port Logic (PL) registers are vendor-specific registers and are used mainly for configuration of PCIe core implementation features, status reporting and testing.

The usage of the Port Logic registers is the same in both EP and RC modes and in the Switch. The Port Logic registers reside in the application register section of the configuration space starting at address 0x700.

48.9.2 Non-Standard Addressing of the iATU Port Logic Registers

See PCIe CTRL Port Logic Memory Map/Register Definition iATU Registers are programmed through an index (Viewport) register to reduce the memory footprint in the PCI Express Extended Configuration Space.

48.9.3 Accessing Configuration Registers (Port Logic Registers)

The application can access the port logic configuration space through the DBI. Bits [11:0] of the DBI address bus select the target register. Host software accesses the configuration registers through PCI Express Configuration Requests.

The Attribute (Attr) column in each register description indicates the read/write access for the register or bit. The table below defines the read/write attribute abbreviations that are used in the register and bit descriptions throughout this chapter.

Table 48-62. Configuration Register Bit-Field Types

Attribute	Description
HwInit	Hardware Initialized HwInit bits are controlled by core hardware and are read-only (RO) by host system software. None of the HwInit bits are writable through the DBI. These bits can only be reset with cold reset. They are not modified by an FLR, or by a warm or hot reset.
RO	Read-Only

Table continues on the next page...

Table 48-62. Configuration Register Bit-Field Types (continued)

Attribute	Description
	Register bits are read-only and cannot be altered by software. Register bits are permitted to be initialized by core hardware. None of the RO bits are writable through the DBI.
RW	Read-Write Register bits are read-write and may be read and written normally by the host and the application. Writing from the application side (if any) requires careful synchronization with the host software.
RW1C	Read-Only Status/Write-1-to-Clear Status Register bits indicate status when read. A set bit indicates a status event may is cleared by writing a 1. Writing 0 to RW1C bits has no effect. Writing from the application side (if any) requires careful synchronization with host software.
ROS	Sticky Read-Only Register bits are read-only and cannot be altered by host or application software, except as noted. Registers are not initialized or modified by a hot reset or FLR. A few bits designated as very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RWS	Sticky Read-Write Register bits are read-write and are set or cleared by host or application software to the desired state. Bits are not initialized or modified by a hot reset or FLR. A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RW1CS	Sticky Read-Only Status/Write-1-to-Clear Status Register bits indicate status when read. A set bit indicates a status event which is cleared by writing a 1, except as noted. Writing 0 to RW1CS bits has no effect. Bits are not initialized or modified by a hot reset or FLR. A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.
RsvdP	Reserved and Preserved Reserved for future RW implementations. Registers are read-only and return zero when read. Software must preserve the value read when writing to other bits in the same register.
RsvdZ	Reserved and Zero Reserved for future RW1C implementations. Registers are read-only and return zero when read. Software must write 0 to these bits when writing to other bits in the same register.
PF	Physical Function Indicates that this Virtual Function (VF) register bit inherits it's value from the corresponding parent Physical Function.

Some of the Port Logic registers are in the sticky reset domain. Sticky registers should not be reset after a warm or hot reset.

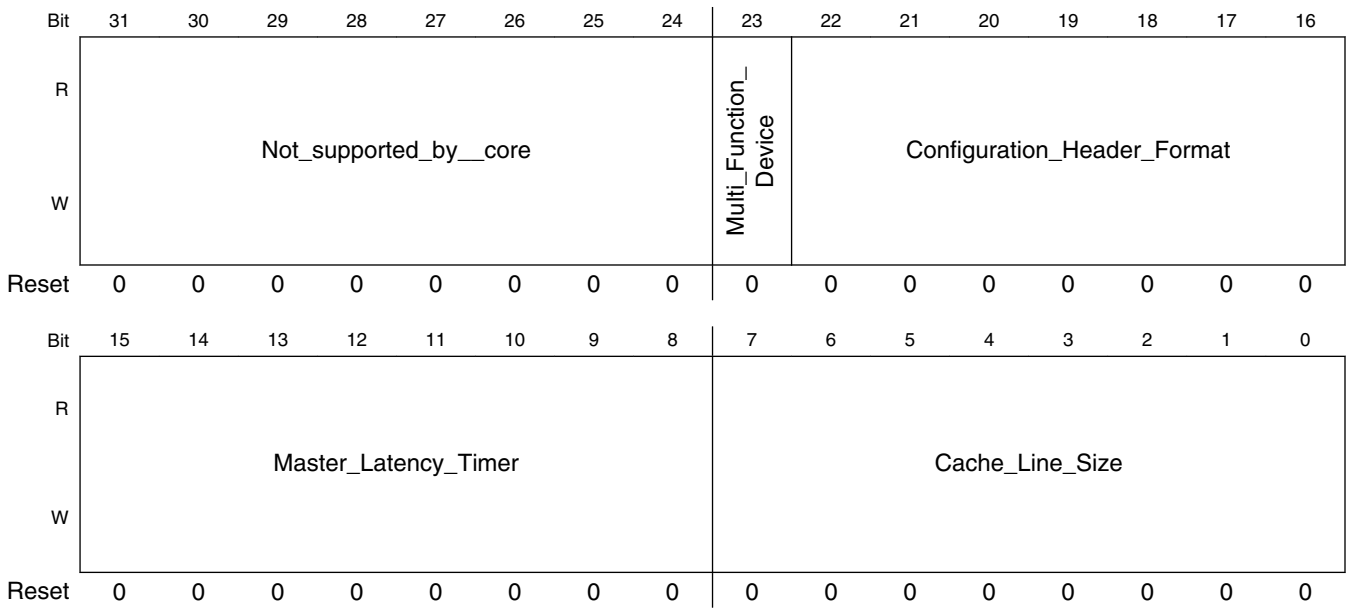
48.10.3 BIST Register (PCIE_EP_BIST)

Offset: 0x0C

Byte: 0

Address: 1FF_C000h base + Ch offset = 1FF_C00Ch



PCIE_EP_BIST field descriptions

Field	Description
31–24 Not_supported_by__core	The BIST register functions are not supported by the core. All 8 bits of the BIST register are hardwired to 0.
23 Multi_Function_Device	Multi Function Device The default value is 0 for a single function device (`CX_NFUNC = 1) or 1 for a multi-function device (`CX_NFUNC != 1). The Multi Function Device bit is writable through the DBI.
22–16 Configuration_Header_Format	Configuration Header Format Hardwired to 0 for type 0.

Table continues on the next page...

PCIE_EP_BIST field descriptions (continued)

Field	Description
15–8 Master_Latency_Timer	Master Latency Timer Not applicable for PCI Express, hardwired to 0.
Cache_Line_Size	Cache Line Size The Cache Line Size register is RW for legacy compatibility purposes and is not applicable to PCI Express device functionality. Writing to the Cache Line Size register does not impact functionality of the core.

48.10.4 Base Address 0 (PCIE_EP_BAR0)

Offset: 0x10-0x24

The core provides three pairs of 32-bit BARs for each implemented function. Each pair (BARs 0 and 1, BARs 2 and 3, BARs 4 and 5) can be configured as follows:

- One 64-bit BAR: For example, BARs 0 and 1 are combined to form a single 64-bit BAR.
- Two 32-bit BARs: For example, BARs 0 and 1 are two independent 32-bit BARs.
- One 32-bit BAR: For example, BAR 0 is a 32-bit BAR and BAR 1 is either disabled or removed from the core altogether to reduce gate count.

In addition, you can configure each BAR to have its incoming Requests routed to either:

- RTRGT1
-

The following sections describe how to set up the BAR types and sizes by programming values into the base address registers. For more information about routing Requests to either RTRGT1 on a BAR-by- BAR basis, see Receive Filtering.

The contents of the six BARs determine the BAR configuration. The reset values of the BARs are determined by hardware configuration options.

At runtime, application software can overwrite the BAR contents to reconfigure the BARs (unless the affected BAR is removed during hardware configuration). Application software must observe the rules listed below when writing to the BARs.

The rules for BAR configuration are the same for all three pairs. Using BARs 0 and 1 as the example pair, the rules for BAR configuration are:

- Any pair (for example, BARs 0 and 1) can be configured as one 64-bit BAR, two 32-bit BARs, or one 32-bit BAR.

- BAR pairs cannot overlap to form a 64-bit BAR. For example, you cannot combine BARs 1 and 2 to form a 64-bit BAR.
-
- An I/O BAR must be a 32-bit BAR and cannot be prefetchable.
- If the device is configured as a PCI Express Endpoint (not a Legacy Endpoint), then any memory that is configured as prefetchable must be a 64-bit memory BAR.
- If BAR 0 is configured as a 64-bit BAR:

- BAR 1 is the upper 32 bits of the combined 64-bit BAR formed by BARs 0 and 1. Therefore, BAR 1 must be disabled and cannot be configured independently.
- BAR 0 must be a memory BAR and can be either prefetchable or non-prefetchable.
- The contents of the BAR 0 Mask register determine the number of writable bits in the 64-bit BAR, subject to the restrictions described in BAR Mask Registers . The BAR 1 Mask register contains the upper 32 bits of the BAR 0 Mask value.
- BAR 0 can be disabled by writing 0 to bit 0 of the BAR 0 Mask register

- If BAR 0 is configured as a 32-bit BAR:

- You can configure BAR 1 as an independent 32-bit BAR
- BAR 0 can be configured as a memory BAR or an I/O BAR.
- The contents of the BAR 0 Mask register determine the number of writable bits in the 32-bit BAR 0, subject to the restrictions described in BAR Mask Registers.
- BAR 0 can be disabled by writing 0 to bit 0 of the BAR 0 Mask register

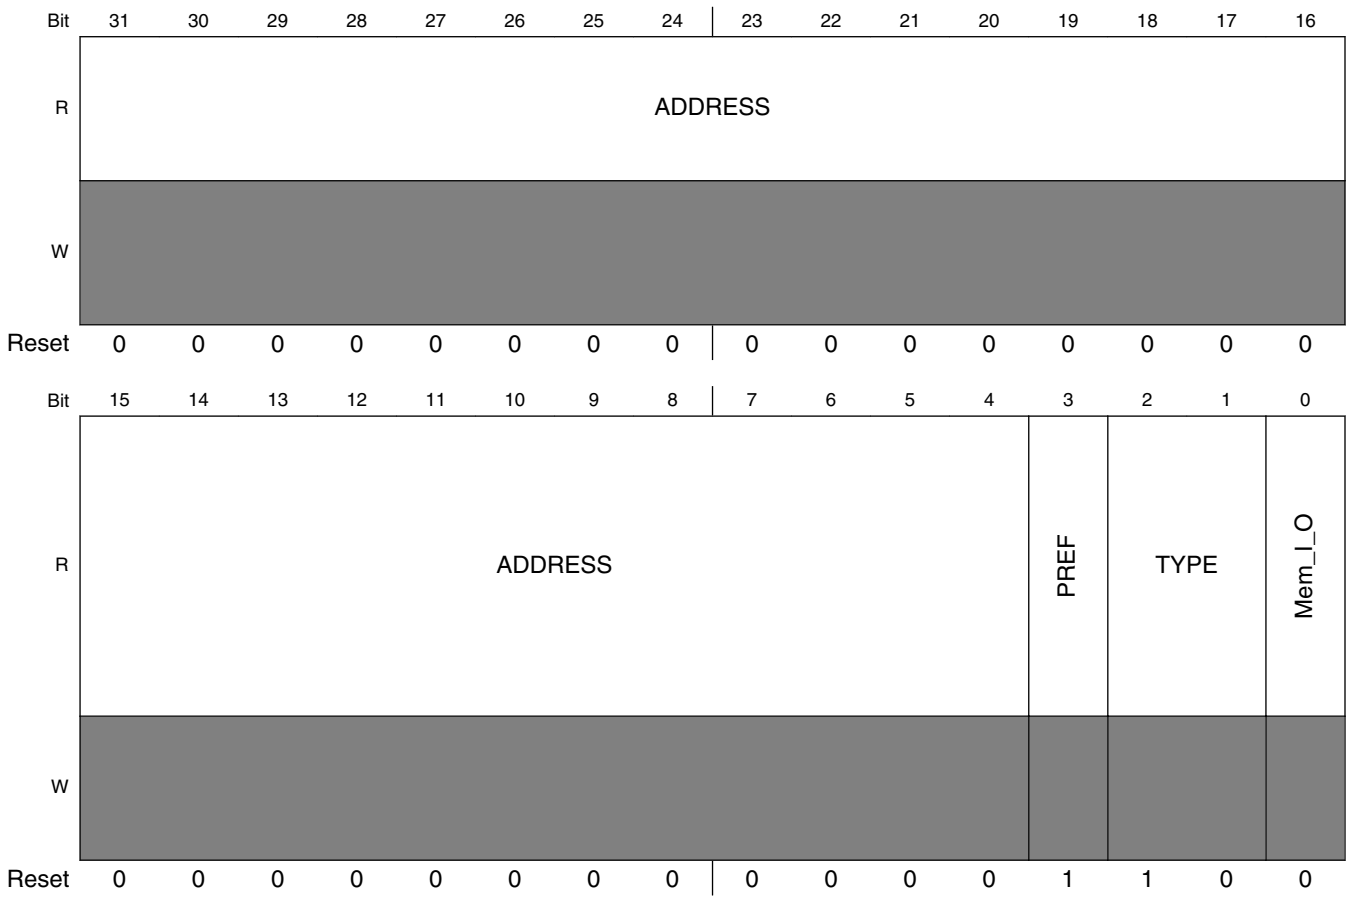
- When BAR 0 is configured as a 32-bit BAR, BAR 1 is available as an independent 32-bit BAR according to the following rules:

- BAR 1 can be configured as a memory BAR or an I/O BAR.
- The contents of the BAR 1 Mask register determine the number of writable bits in the 32-bit BAR 1, subject to the restrictions described in BAR Mask Registers.
-
-

The same rules apply for pairs 2/3 and 4/5.

Offset: 0x10 (if included in the core hardware configuration)

Address: 1FF_C000h base + 10h offset = 1FF_C010h



PCIE_EP_BAR0 field descriptions

Field	Description
31–4 ADDRESS	BAR 0 base address bits (for a 64-bit BAR, the remaining upper address bits are in BAR 1). The BAR 0 Mask value determines which address bits are masked.
3 PREF	If BAR 0 is an I/O BAR, bit 3 is the second least significant bit of the base address. Bits [3:0] are writable through the DBI. If BAR 0 is a memory BAR, bit 3 indicates if the memory region is prefetchable: 0 = Non-prefetchable 1 = Prefetchable
2–1 TYPE	If BAR 0 is an I/O BAR, bit 2 the least significant bit of the base address and bit 1 is 0. Bits [3:0] are writable through the DBI. If BAR 0 is a memory BAR, bits [2:1] determine the BAR type: 00 = 32-bit BAR 10 = 64-bit BAR
0 Mem_I_O	Bits [3:0] are writable through the DBI. 0 = BAR 0 is a memory BAR 1 = BAR 0 is an I/O BAR

48.10.5 BAR 0 Mask Register (PCIE_EP_MASK0)

The BAR masks are used for indicating the amount of memory each BAR requests from host software. The application logic can overwrite the default values via the DBI.

The BAR Mask registers determine which bits in each BAR are non-writable by host software, which determines the size of the address space claimed by each BAR.

The BAR Mask values indicate the range of low-order bits in each implemented BAR not to use for address matching. The BAR Mask value also indicates the range of low-order bits in the BAR that cannot be written from the host. The application can write to all BAR bits to allow setting of memory, I/O, and other standard BAR options.

To disable any BAR, the application can write a 0 to bit 0 of the corresponding BAR Mask register. To change the BAR Mask value for a disabled BAR, the application must first enable the BAR by writing 1 to bit 0. After enabling the BAR, the application can then write a new value to the BAR Mask register.
